

This is a digital copy of a book that was preserved for generations on library shelves before it was carefully scanned by Google as part of a project to make the world's books discoverable online.

It has survived long enough for the copyright to expire and the book to enter the public domain. A public domain book is one that was never subject to copyright or whose legal copyright term has expired. Whether a book is in the public domain may vary country to country. Public domain books are our gateways to the past, representing a wealth of history, culture and knowledge that's often difficult to discover.

Marks, notations and other marginalia present in the original volume will appear in this file - a reminder of this book's long journey from the publisher to a library and finally to you.

Usage guidelines

Google is proud to partner with libraries to digitize public domain materials and make them widely accessible. Public domain books belong to the public and we are merely their custodians. Nevertheless, this work is expensive, so in order to keep providing this resource, we have taken steps to prevent abuse by commercial parties, including placing technical restrictions on automated querying.

We also ask that you:

- + *Make non-commercial use of the files* We designed Google Book Search for use by individuals, and we request that you use these files for personal, non-commercial purposes.
- + *Refrain from automated querying* Do not send automated queries of any sort to Google's system: If you are conducting research on machine translation, optical character recognition or other areas where access to a large amount of text is helpful, please contact us. We encourage the use of public domain materials for these purposes and may be able to help.
- + *Maintain attribution* The Google "watermark" you see on each file is essential for informing people about this project and helping them find additional materials through Google Book Search. Please do not remove it.
- + *Keep it legal* Whatever your use, remember that you are responsible for ensuring that what you are doing is legal. Do not assume that just because we believe a book is in the public domain for users in the United States, that the work is also in the public domain for users in other countries. Whether a book is still in copyright varies from country to country, and we can't offer guidance on whether any specific use of any specific book is allowed. Please do not assume that a book's appearance in Google Book Search means it can be used in any manner anywhere in the world. Copyright infringement liability can be quite severe.

About Google Book Search

Google's mission is to organize the world's information and to make it universally accessible and useful. Google Book Search helps readers discover the world's books while helping authors and publishers reach new audiences. You can search through the full text of this book on the web at <http://books.google.com/>

Civil engineers' pocket book

Albert Irvin Frye

CIVIL ENGINEERS' POCKET-BOOK.

A REFERENCE-BOOK FOR ENGINEERS
CONTRACTORS AND STUDENTS
CONTAINING RULES, DATA
METHODS, FORMULAS
AND TABLES

BY

PREFACE.

The preparation of notes for this volume was begun several years ago, while chief engineer of the Hoffman & Bates Bridge and Construction Company, and has been continued systematically up to the present time.

Three separate systems of note-keeping have been employed, namely: (1) Two blank-books, size eight by twelve and one-half inches, with quadrangular ruling and marginal index, were started, one for mathematical and structural data and the other for general construction notes, each book containing five hundred pages in flexible leather binding. (2) Note books of the same general style, but of pocket size, were classified—for bridges, buildings, water-works, sewers, surveys, etc.—and kept at hand for general reference and memoranda. (3) The loose-leaf method was inaugurated and found to be specially useful in consulting practice. The last named is explained in an article prepared for the "Engineering Record" and published in the issue of January 21, 1911.

In 1904, the present system was outlined—arranging the matter logically in numbered Sections for convenient reference. From that time up to the present, the work has gradually been crystallized and brought up to date.

Special attention is invited to the vast number of tables, their completeness and arrangement. Although most of them have never before appeared in print—at least in their present form—yet nearly all of them have been subjected to the test of more or less constant use for a number of years, in connection with practical work. All of them have been thoroughly checked—the proofs of all were checked twice before electrotyping, and the proofs of the most important ones were checked again after electrotyping.

The logarithmic tables comprise both the common and hyperbolic systems, side by side, the latter being useful in certain bridge calculations and in steam engineering. Both the logarithmic and trigonometric tables are carried out to five decimal places, a sufficient refinement for most engineering opera-

tions, being much more exact than actual measurements in shop or field.

The tables of cubes and squares, in Section 33, will be found useful to structural detailers. They were calculated by the incremental additive method, which is self-checking.

The text is so arranged that all general data may be found readily from the Table of Contents, which should be consulted as frequently as the Index, the latter being necessary for more specific reference. The number and title of each Section appear as even-page captions throughout the work. The tables and illustrations are numbered from one upward for each Section. It has been the aim to begin each subject and paragraph with the leading or key word, as a supplementary page index.

At the end of most of the Sections will be found references to valuable data in leading technical publications, which should be in the library of every engineer. The reader is advised to supplement this data with his own lists, perhaps in a separate note book, under the respective Section numbers.

Acknowledgments are due to Mr. Paul D. Ford, for his kindness in volunteering to read over portions of the manuscript while in preparation, and making many valuable suggestions; also to Professor C. H. Peabody, for permission to use the steam tables and other material in Section 69; and to many others whose names appear in the body of the work, where specific credit is given.

The Publishers, Electrotypers and Printers are to be congratulated on the neat appearance of the book, and the author desires to thank Mr. Jacob Wernli for his excellent work in preparing the illustrations.

ALBERT I. FRYE.

New York, December, 1912.

CONTENTS.

(Page numbers are given. For Alphabetical Index, see page 1539.)

Introduction	XXIX
Signs and Abbreviations	XXXVII

SEC. 1.—ELEMENTARY ARITHMETIC.

Numbers—Roman System, Arabic System.....	1
Primes, Multiples and Factors, 2; Table.....	3
Greatest Common Factor; Least Common Multiple.....	6
Fractions, 7; Reduced to Decimals, Tables.....	9
Decimals, 10; Repeating Decimals.....	11
Short Methods of Multiplication—Fractions and Decimals.....	11
Cancellation.....	13

SEC. 2.—POWERS, ROOTS AND RECIPROCALLS.

A.—Engineers' Tables.

Square Root, 14; Square Roots (and Squares) of Numbers, Tables....	16
Cube Root, 20; Cube Roots (and Cubes) of Numbers, Tables.....	21
Square Roots of Fifth Powers of Numbers, Table.....	25
Fifth Powers (and Fifth Roots) of Numbers, Table.....	26
Reciprocals of Numbers, 30; Table.....	28

B.—Arithmetical or Common Tables.

Squares, Cubes, Square Roots, Cube Roots of Numbers 1-1600, Table..	31
Square Roots and Cube Roots of Numbers 1600-3200, Table.....	44
Reciprocals of Numbers 1-1000, Table.....	51

SEC. 3.—PRACTICAL ARITHMETIC.

Proportion, 55; Permutation, Combination, 56; Allegation, Progression	57
Percentage, Interest, Discount, 58; Simple Interest Table.....	60
Table for Finding Number of Days Between Any Two Dates.....	61
Equation of Payments, 61; Compound Interest Table.....	62
Partial Payments, Annuities, Sinking Fund, 63; Tables.....	64, 65

SEC. 4.—MEASURES, WEIGHTS AND MONEY.

Fundamental Units.

Meter—Length, Area, Volume.....	66
Liter—Capacity (Liquid and Dry).....	66
Gram—Mass (Weight).....	67

General Tables.

Approximate Equivalents—Metric and English.....	68
English Measures, Metric Equivalents—Long, Surveyors', Mariners'..	68
Lengths—Inches and Millimeters.....	69, 70
Lengths—Metric Table; Metric and English, Equivalents (1-9).....	70
Lengths—Feet and Inches to Meters, 71; Meters to Feet.....	75
Areas—Metric Table; Metric and English, Equivalents (1-9).....	79, 80
Areas—English Land Measure, Texas Land Measure.....	81
Measures and Weights of the Philippines, English Equivalents.....	81
Volumes—Metric Table; Metric and English, Equivalents (1-9).....	81, 82
Volumes—English Cubic Measure, Metric Equivalents.....	82
Capacities (Liquid)—Metric Table; Metric and English, Equiv. (1-9).....	82, 83
Capacities (Liquid)—Liquid and Apothecaries' Measures.....	83
Capacities (Dry)—Metric Table; Metric and English, Equivalents (1-9)	84
Capacities (Dry)—English Dry Measure, Metric Equivalents.....	84
Weights—Metric Table; Metric and English, Equivalents (1-9).....	85
Weights—Apothecaries, Troy, Avoirdupois—Metric Equivalents.....	86
Weights—Various Tons and Pounds, Equivalents (1-9).....	87
Simple and Compound Units in Common Use, Equivalents.....	88
Electrical, Mechanical and Heat Units—Equivalents.....	91
Foreign Weights and Measures, American Equivalents.....	92
Numbers—Abstract, Duodecimo, Paper—Tables.....	95

Money—Domestic and Foreign.....	95
Money—Value of Foreign Coins, American Equivalents	96
Prices—Comparison of German for Metric; British; and American	98
Time Measure; Circular Measure	99

SEC. 5.—ALGEBRA.

Exponents.....	100
Binomial Formula, 101; Completing the Square.....	102
Simultaneous Equations.....	103

SEC. 6.—LOGARITHMS OF NUMBERS.

Common System—Described, 104; Operations, 105; Table.....	108
Naperian System—Described, 104; Operations, 106; Table.....	108
Slide Rules.....	126

SEC. 7.—PLANE GEOMETRY.

Angles and Lines; Triangles; Quadrilaterals.....	128
Polygons (General); Regular Polygons; Circle	129
Problems in Construction of Figures.....	130

SEC. 8.—SOLID GEOMETRY.

Planes, Angles and Lines; Polyhedrons.....	132
Prisms and Pyramids.....	133
Cylinders, Cones and Spheres.....	134

SEC. 9.—PLANE TRIGONOMETRY.

Trigonometric Functions—Formulas.....	136
Values of Trigonometric Functions in the Four Quadrants.....	137
Natural Functions of Angles in the Four Quadrants.....	138
Functions of Complement, Supplement, etc., of any angle x	139
Functions of the Sum and Difference of Two Angles, x and y	139
Functions of one-half x , $2x$, $3x$ and $4x$	140
Inverse Trigonometric Functions.....	140
Solution of Right Angle Triangles.....	141
Solution of any Triangle.—Circular Measure.....	142
Cubic Equations.....	143
Table of Natural Sines, Tangents, Cotangents, Cosines, etc.....	144
Table of Natural Secants, Cosecants, Exsecants and Coexsecants.....	167
Table of Logarithmic Sines, Tangents, Cotangents, Cosines, etc.....	176
Table for Finding the Logarithmic Sines and Tangents of Small Angles.....	198

SEC. 10.—SPHERICAL TRIGONOMETRY.

Functions; Right Spherical Triangles, Formulas.....	199
Oblique Spherical Triangles—Formulas and Rules.....	200
Distance Between Two Points on the Earth's Surface.....	201
The Celestial Sphere, 201; Astronomical Time, Tables.....	202

SEC. 11.—MENSURATION.

A.—Plane Surfaces, Lines, etc.

Triangle and Quadrilateral.....	203
Regular Polygon, and Table; Circle.....	204
Tabular Values of Combinations of x , with Logs.....	205
Arc and Chord of Circle, 207; Lengths of Circular Arcs.....	208
Lengths of Circular Arcs for Radius 1, Table.....	209
Lengths of Circular Arcs for Chord 1, Table.....	210
Flat Circular Arc, Formulas and Tables.....	211
Circular Segments—Formulas, 214, 215; Tables	216-218
Circular Ring and Circular Zone, Properties of.....	219
Circular Lune; Circular Sector; Circle and Square, Relations of.....	220
Table of Relations of Circle and Square.....	221
Decimals of a Foot for Each $\frac{1}{16}$ of an Inch, Table.....	222
Table of Circles—Circumferences for Given Diameters, Decimals.....	225
Table of Circles—Circumferences for Diameters in Feet or Inches.....	226
Table of Circles—Areas for Given Diameters in Inches and Fractions..	230
Table of Circles—Areas for Given Diameters, Decimals.....	232
Table of Circles—Areas (Sq. Ft.) for Given Diameters (Ft., Ins.).....	234
Cycloid.....	236
Parabola, Parabolic Segment, Parab'c Half-Segment, Parab'c Spandrel.....	237

Lengths of Parabolic Arcs for Chord (Base) 1, Table.....	238
Ellipse, 238; Formulas for Circumference of Ellipse.....	239
Lengths of Semi-Elliptic Arcs, Table.....	241
Segment and Chord of Ellipse.....	242

B.—Solids.

Pappus's Theorem.—Prismoidal Formula.....	243
The Five Regular Polyhedrons, Table.....	243
Prisms and Cylinders; Frustums of Prisms and Cylinders.....	244
Circular Cylindric Wedges and Half-Wedges.....	245
Properties of Hollow Cyl's (Pipes, Tanks, Wells), One Foot Long, Table.....	246
Pyramids and Cones; Frustums of Pyramids and Cones.....	248
Conic Wedge and Frustum; Wedge; Sphere.....	249
Areas of the Surfaces of Spheres, Table.....	251
Volumes of Spheres, Table.....	252
Spherical Segment, 252; Spherical Zone.....	253
Hollow Sphere; Circular Segmental Ring.....	253
Regular Circular Ring; Circular Spindle.....	253
Parabolic Spindle; Cycloidal Spindle; Paraboloid.....	254
Ellipsoid.....	255

SEC. 12.—ANALYTIC GEOMETRY.

Straight Line.....	256
Circle; Parabola.....	257
Ellipse.....	258
Hyperbola, 259; Equilateral Hyperbola.....	260
Cycloid; Spiral of Archimedes; Logarithmic Spiral.....	260
Hyperbolic Spiral; Lemniscate of Bernoulli.....	260
Helix or Screw; Common Spiral.....	260

SEC. 13.—DESCRIPTIVE GEOMETRY.

Perspective; Cabinet-, Isometric-, Orthographic Projection.....	261
Revolved Planes; Projection of the Point.....	262
Projection of the Right Line; Projection of Two Lines.....	262
Projection of the Plane; Problems of Construction.....	263

SEC. 14.—THE CALCULUS.

A.—Differential Calculus.

Differentiation and Differential Coefficient, Defined.....	266
Tangent and Normal; Rules for Differentiation.....	267
Maxima and Minima, with Problems.....	268, 269
Differentiation of Logarithmic and Exponential Functions.....	270
Differentiation of Trigonometric Functions.....	270
Differentiation of Inverse Trigonometric Functions.....	271
Expansion of Functions—By Division, Successive Differentiation.....	271
Maclauren's Theorem.....	271
Taylor's Theorem.....	272

B.—Integral Calculus.

Integration as a Summation, Defined.....	272
Definite Integration a Method of Limits.....	273
Formulas for Integration.....	274
Areas and Lengths of Plane Curves, Problems.....	275
Areas of Curved Surfaces, Problem.....	276
Volumes, or Planes of Revolution.....	277

SEC. 15.—MECHANICS.

Fundamental Equations of Motion and Force.....	278
--	-----

Motion Formulas.

Uniform Motion, No Acceleration.....	279
Uniformly Accelerated Motion, No Initial Velocity.....	279
Uniformly Accelerated Motion with Positive Initial Velocity.....	280
Uniformly Accelerated Motion with Negative Initial Velocity.....	282
Table of Falling Bodies [See, also, Table on page 1155].....	283
Summary of Preceding Motion Formulas.....	284
The Resultant of Two Constant Velocities.....	284
Parabolic Motion—Path of Projectile.....	285
Circular Motion—Fly-Wheel.....	286

Motion on Inclined Plane.....	286
Motion on Cycloidal Curve.....	286
Simple and Compound Circular Pendulums.....	287
Simple Cycloidal Pendulum.....	287

Dynamic Formulas.

Force—Fundamental Relations.—Atwood's Machine.....	288
Force—General Relations, Distance Included.....	289
Work—Hoisting-Rope Problem.....	290
Power—Locomotive Problem.....	291
Leverage—Simple Lever.....	291
Compound Lever; Inclined Plane; Wedge.....	292
Screw; Pulley, Simple and Compound.....	292
Toggle.—Impulse and Momentum.—Energy.....	293
Composition and Resolution of Forces.....	294
Principles of Equilibrium.....	294
Polygon of Forces; Moments and Reactions.....	295
Center of Gravity and Resultant of a System of Parallel Forces.....	295
Resultant of a Distributed Force—Problem.....	296
Centrifugal Force—Fly-Wheel Problem.....	297
Centrifugal Force—Elevation of Outer Rail on Curve.....	298

Forces Acting on Plane Surfaces.

Bending Moment and Resisting Moment.....	298
Resisting Moment and Moment of Inertia.....	299
Moment of Inertia and Radius of Gyration.....	299
Radius of Gyration and Moment of Inertia.....	300
Resistance of Rectangular and Circular Beams Compared.....	301

Forces Acting on Solids.

Moment of Inertia of Solid Body, Defined.....	302
Moments of Inertia of Regular Solids, Table.....	302
Radius of Gyration of Solids.....	302
Center of Gravity of Solids.....	303
Center of Oscillation—Center of Percussion.....	303
Impact or Collision, 303; Formulas.....	304

SEC. 16.—THEORY OF STRESSES IN STRUCTURES.

Outer and Inner Forces—Loads, Reactions, Stresses.....	305
Principles of Static Equilibrium.....	305
Methods of Calculation—By Moments, Shears, Graphics.....	306

Loads and Reactions Vertical.

Pratt Truss Calculation—Dead Load Stresses.....	306
Reaction at Left Support; Lengths of Members.....	307
Trigonometric Ratios for Calculating Chord and Web Stresses.....	307
Stresses in Chord Members by Method of Moments—Rules.....	307
Stresses in Web Members by Method of Shears—Rules.....	308
Static Equilibrium of Inner and Outer Forces at Joints.....	309
Bow's Notation in Graphical Statics.....	309
Graphical Method.....	310
General Rules for Stress Diagrams.....	310
Order of Considering Joints.....	311
Graphical Solution of Pratt Truss, with—.....	312
Loads at Top Joints; Loads at Top and Bottom Joints.....	313

Reactions in Any Direction.

Roof Truss, Both Ends Fixed, Wind on One Side.....	314
Roof Truss, One Roller End, Wind on Either Side.....	314
Three-Hinged Arch, Vertical Loads.....	315

SEC. 17.—NATURAL HISTORY OF MATERIALS.

A.—Chemical.

Composition of Matter.—The Old Atomic Theory.....	316
Recent Discoveries.—The Corpuscular Theory.....	316
The Electronic Theory.—The Chemical Elements.....	317
Table of the Chemical Elements.....	318
Compounds.—Simple Combinations.....	321
Acids, Bases and Salts; Oxides and Hydroxides.....	321
Acid Combinations.....	321

Periodic Law, 322; Natural System of the Elements.....	323
Chemical Substances and their Common Names.....	324

B.—Mineralogical.

Minerals—Hardness and Other Physical Characteristics.....	324
Classification of Important Mineral Species.....	325-328
Native Elements; Sulphides; Chlorides, Bromides, Iodides.....	325
Oxygen Compounds—Oxides, Silicates.....	326
Oxygen Compounds—Phosphates, Borates, Sulphates, Carbonates.....	327
Hydrocarbons—Petroleum, Naphthalin, Asphaltum, Coal.....	328
Blowpipe Characteristics of Minerals.....	328
Some of the Important Minerals, Table.....	328
Minerals—Gold, Silver, Potassium, Sodium.....	328
Minerals—Lithium, Platinum, Iridium.....	328
Minerals—Mercury, Copper, Iron, Cadmium, Zinc.....	329
Minerals—Lead, Cobalt, Nickel, Manganese, Calcium.....	329
Minerals—Magnesium, Tin, Titanium, Thorium, Arsenic.....	330
Minerals—Antimony, Bismuth, Sulphur, Tellurium, Uranium.....	330
Minerals—Molybdenum, Aluminum, Boron, Hydrogen, Carbon.....	330
Silica Minerals—Granite, Sandstone, Bluestone, Slate.....	331
Silica Minerals—Fibrous Talc, Compact Talc, Mica, Asbestos.....	331
Silica Minerals—Serpentine, Feldspar, Quartz, Infusorial Earth.....	331
Silica Minerals—Kaolinite, Clay, Fuller's Earth.....	331
Lithology—Rocks and Rock-Formations.....	331
Principal Rock-Forming Minerals, Table.....	332
The Common Rocks, 333; Table of Composition, Texture, etc.....	334
The Common Rocks—Notes on Preceding Table.....	339

C.—Botanical.

Acreage of Timber Land in the United States.....	340
Classification of Important Trees, Table.....	341-346
Trees—Soft Pines, Pitch Pines, Larches, Spruces.....	341
Trees—Spruces, Hemlocks, Firs, Redwoods, Cedars, Cypressess.....	342
Trees—Cypressess, Walnuts, Hickories, Poplars.....	343
Trees—Poplars, Willows, Birches, Beeches, Chestnuts, White Oaks.....	344
Trees—White Oaks, Black Oaks, Elms, Sweet Gums.....	345
Trees—Maples, Ashes.....	346
Tree Data—Tallest, Best, Ages, Growth, Important Products.....	346

D.—Zoological.

Animal Species and their Uses to Man.....	347
Classification of Animals, Table.....	347-349

SEC. 18.—EXPLOSIVES.**(a).—Mechanical Mixtures.**

Nitrate Mixtures, Gunpowder, Blasting Powder.....	350
Weight of Powder in a Hole One Foot Deep, Table.....	350
Chlorate Explosive Mixtures.....	351

(b).—Chemical Compounds.

Nitro Substitution Explosives; Nitric-Acid Compounds; Guncotton....	351
Detonation; Smokeless Powders; Nitroglycerin; Dynamite.....	352
Unmixed Explosives; Percussion Caps.....	353
The Handling and Use of Dynamite.....	353
Some of the Most Common Commercial Dynamites.....	354
List of Permissible Explosives for Use in Coal Mines.....	354

SEC. 19.—PRESERVATIVES.**Paints.**

Pigments—Lead, Zinc, Lampblack, Boneblack, Graphite, Iron, etc.....	355
Vehicles—Linseed Oil.....	355, 356
Driers; Solvents—Turpentine.....	356
House Paints—Mixtures—Colors, Table.....	356
Special Paints—Aluminum.....	356
Special Paints—Bronze, Copper.....	357

Varnishes, Lacquers, etc.

Varnishing; Laquering; Japanning.....	357
---------------------------------------	-----

Galvanizing and Tinning.

Galvanizing; Tinning—Tin Plate, Terne Plate.....	357
--	-----

Electro-Plating.

Electro-Chemistry; Electrolysis; Electro-Metallurgy.....	357
Electro-Plating—Gold, Silver, Copper, Nickel, etc.....	358

Preservation of Steel and Iron.

Oiling, Painting, Asphalting; Removing Mill Scale.....	358
--	-----

Preservation of Timber.

Sources of Decay—Wet Rot, Fermentation, Dry Rot, Insect Larvæ....	359
Piling; Creosoting; Burnettizing; Miscellaneous Notes.....	360
Seasoning—Distribution of Water in Timber.....	361
Seasoning—Relation of Water to Decay; What Seasoning Is.....	362
Seasoning—Preservative Treatment; Advantages; Methods.....	363
Seasoning—Conclusions and Recommendations.....	365

Creosote in Well-Preserved Timbers.

Manufacture and Composition of Creosote.—Coal Tar.....	365
Analyses of Creosote Extracted From Well-Preserved Timber.....	367
Results of Analyses of Extracted Oils, Table.....	368

Excerpts and References.

Protection of Ferric Structures from Corrosion.....	372
Painting and Sand-Blast Cleaning of Steel Bridges, Costs.....	373
Creosoting Wooden Poles for Electric Line-Work, Costs.....	373
Corrosion of Steel in Reinforced Cinder Concrete.....	374
Cleaning Steelwork by Sand-Blast, Painting by Compressed Air, Costs.....	374
Comparison of Various Processes of Preserving Timber, Costs.....	375

SEC. 20.—LUMBER AND LUMBERING.

Stumpage in the United States, Tables.....	376
Range of Lumber Prices for Twenty Years.....	377
Logging—Trees, Time for Cutting, Volume of Standing Timber.....	378
Logging—Transportation of Logs, 378; Scaling Logs.....	379
Lumber—Sawing, Sizing, Planing, Seasoning, Board Measure.....	379
Table of Feet Board Measure of Lumber.....	380-387
Grading of Lumber.....	387
Classification and Inspection of Yellow Pine Lumber.....	387
Rules for Grading Fir, Spruce, Cedar and Hemlock Lumber.....	388
Shingles—Grades and Specifications.....	390
Graphical Comparison of Various Log Rules.....	391
Commercial Shipping Weights of Various Kinds of Lumber.....	391

SEC. 21.—METALLURGY.

Iron Ore; Pig Iron; Cast Iron.....	392
Cast Steel; Malleable Castings; Wrought Iron.....	393
Steel—Various Processes—Acid-Bessemer.....	394
Steel—Basic Bessemer, Acid Open Hearth, Basic Open Hearth.....	395
Steel—Cementation Process; Shear Steel; Crucible Cast Steel.....	395
Steel—Open Hearth Cast-, Harveyized-, Vanadium-.....	396
Steel—Chrome-, Nickel-, Tungsten-.....	396
Alloys of Various Metals.....	396
Bronze—Phosphor-, Manganese-, Aluminum-, Silicon-.....	397
Brass—Copper-Zinc Alloys, Table.....	397
Tin-base Alloys; Lead-base Alloys; Alzene.....	398
Malleable Cast Iron; Nickel Steel, Properties.....	398
Vanadium Steel—Structural—Alloys.....	399

SEC. 22.—BUILDING STONES AND CEMENTS.**Natural Building Stones.**

Granite, Basalt, Trap, Greenstone, Limestone.....	400
Carbonate of Lime, Dolomite, Hydraulic Limestone.....	401
Marl, Travertine, Marble (Domestic and Foreign).....	401
Sandstone (Berea, Medina, Potsdam, Conn. Val., N. J.).....	401
Sandstone, Frost Test; Flagstone; Slate.....	401

Cements (Miscellaneous).

Materials with Cementing Properties.....	402
Cements—Boiler, Coppersmith's, Fireproof, Flour, Gas Fitters'.....	402
Cements—Iron, Glue, Steam-Pipe.....	402
Cements—Keene's Marble.....	405

Cements (Builders).

Calcium, Lime, Common Lime, Lime Mortar, Lime Plaster.....	403
Plaster of Paris, Hydraulic Lime.....	404
Hydraulic Cement—Natural, Portland, Slag.....	404
Bitumen, Asphalt.....	404
Manufacture of Portland Cement—Wet and Dry Processes.....	405
Calcination—Rotary Kiln; Grinding the Clinker.....	405
Requisites of a Cement in Cement Testing.....	406
Method of Testing Cement—A. S. C. E. and A. S. T. M.—.....	407
Selection of Sample, Specific Gravity, Fineness.....	407
Normal Consistency—Vicat Needle Test.....	408
Percentage of Water for Standard Sand Mortars.....	409
Time of Setting; Standard Sand.....	409
Form of Briquette; Molds; Mixing.....	410
Molding; Storage of the Test Pieces.....	410
Tensile Strength; Constancy of Volume.....	411
Specifications for Cement—A. S. T. M.—.....	411
Specifications—Natural Cement, Portland Cement.....	412
Specifications for Cement—Engrs. U. S. A.—.....	413
Specifications—American Portland Cement.....	413
Specifications—Natural Cement Puzzolan Cement.....	414

Artificial Building Stones.

Brick—Common, Face, Glazed, Vitrified, Terra Cotta.....	415
Fire Brick, Paving Brick, Sewer Brick.....	415
Concrete—Kinds, Mixture, Proportions, Voids, Economy.....	416
Concrete—Cement-Sand Mix, Cement-Sand-Stone Mix.....	417
Concrete—Size of Broken Stone.....	417
Block Stone—Beton-Coignet, Sand Bricks, Portland Stone.....	417
Block Stone—McMurtrie Stone, Ransome Stone, Sorel Stone.....	417

Miscellaneous Data.

Lutes and Cements Useful to Engineers.....	418
Compositions—Water-Proof, Oil-Proof, Acid-Proof, etc.....	418
Cost of Portland Cement.....	418
A Cement which is Proof Against Sea-Water.....	418

SEC. 23.—QUARRYING.

Sand, Gravel, Rip-rap, Stone—Hand Tools, Channeling Machines.....	419
Weight and Specifications of Sullivan Channelers, Table.....	421
Explosives; Rock Drills—Hammer, Churn, Percussion.....	422
Quarrying by Direct Use of Compressed Air.....	423
Cost of Quarrying Rubble and Dimension Stone.....	423
Dimensions and Weights of Rand Percussion Rock Drills, Table.....	424

SEC. 24.—STONE CUTTING.

Stones Classified According to Finish.—Tools Employed.....	426
Unsquarred Stones.—Hand Hammer, Plug and Feathers, etc.....	426
Squared S.; Quarry-Faced S.—Face Hammer; Cavi.....	427
Pitched-Faced S.; Drafted S.—Chisel; Pitching C.; Tooth C.....	427
Cut Stones.—Mallet, Pick, Point, Crandall.....	428
Cut Stones.—Ax, Pean Hammer, Patent Hammer, Tooth Ax.....	429
Cut Stones.—Bush Hammer, Machine Tools.....	430

SEC. 25.—MASONRY.

Kinds of Masonry; Classification of Railroad Masonry, Table.....	431
--	-----

I.—Stone Masonry.

Definitions of Parts of Wall.....	431
Definitions of Kinds of Masonry.....	432
Specifications for Stone Masonry, General.....	433
Specifications for Bridge and Retaining Wall Masonry.....	434
Specifications for Arch Masonry, Culvert M., Dry M.....	435
Quantities of Masonry in Railroad Abutments, Table.....	436
Table for Finding Weights of Quantities in Preceding Table.....	437

II.—Brick Masonry.

Bonds—English, Flemish, etc.; Brickwork.....	437
Mortar Used in Brickwork; Table of Quantities.....	438

III.—Concrete Masonry.

Rock Crushers; Concrete Mixers—Gravity, Mechanical. (Batch).....	439
--	-----

Concrete—Proportions of Cement, Sand and Stone—Mixing.....	440
Concrete—Placing, Spreading and Ramming; Subaqueous C.....	440
Concrete, Subaqueous—Depositing by Tubes, Buckets, Bags.....	441
Sub-Foundations—Prepared by Dredging, Cement Grout.....	442
German Specifications for Concrete.....	442

IV.—Reinforced Concrete.

Uses of Reinforced Concrete.....	443
The Preservative Qualities of Cement.....	444
The Fire-Resisting Qualities of Concrete.....	444
The Proportions Used in Mixing Concrete.....	444
Calculations of Reinforced Concrete Beams.....	444
Formulas; Values of f for Three Standard Mixes.....	445
Properties of Reinforced Concrete Beams 1 Inch Wide, Table.....	446
Formulas for Reinforced Concrete Construction—A. S. C. E.....	446

V.—Mixed Masonry.

Description—Weakness of Bond.....	449
-----------------------------------	-----

VI.—Concrete-Block Masonry.

Solid Concrete Blocks; Hollow Concrete Blocks.....	450
Specifications for Hollow Concrete Building Blocks.....	450

Miscellaneous Data.

Permeability of Concrete Under High Water Pressure.....	453
Waterproofing Data—Concrete in Government Fortifications.....	453
The Efficiency of Concrete-Mixing Machines.....	453
Method of Finishing the Concrete Surfaces of Bridges.....	454
Concrete Bridge—Materials Required for Different Mixes.....	454
Expansion Joints in Concrete Structures—Reservoirs, Drydocks.....	454
Oil-Mixed Concrete as a Waterproofing Material.....	455
Specifications for Scrubbed Concrete Surface.....	455

SEC. 26.—STEREOTOMY.

Wall of Building.—Stone Arch.....	457
-----------------------------------	-----

SEC. 27.—WEIGHTS AND SPECIFIC GRAVITIES OF MATERIALS.

Definitions.

Mass, Unit of Mass, Gravity Acceleration, Weight.....	459
Volume, Density, Specific Gravity.....	460

Methods for Determining Specific Gravity.

Solids Heavier than Water; Solids Lighter than Water.....	460
Displacement Method; Porous Substances.....	460
Granular Substances; Liquids.....	461
Beaumé's Hydrometer, Tweddell's H.; Rousseau's Densimeter.....	461
Nicholson's and Fahrenheit's Hydrometers; Refinements.....	462
Gases—Standard Pressure, Temperature, Substance.....	462

Gases.

Weight of a Cubic Foot of Dry Air at Various Temperatures, Table....	463
Weights and Specific Gravities of Gases, Table.....	464

Liquids.

Weight of a Cubic Foot of Water at Various Temperatures, Table.....	465
Equivalents of Centigrade and Fahrenheit Scales, Table.....	465
Weights and Specific Gravities of Liquids, Tables.....	468, 469

Solids and Miscellaneous.

Weights and Specific Gravities of Woods, Tables.....	470—473
Weights and Specific Gravities of Building Stones, Masonry and Cements, Table.....	474—477
General Table of Weights and Specific Gravities of Materials, Table	478—482
Weights of Produce (U. S. Law), Table.....	482

Reduction Tables.

Weight Equivalent for Any Specific Gravity.....	483
Weight of Sheets, Bars, Wire, for any Specific Gravity.....	484
Weight for Cubic Yard for Any Specific Gravity.....	484
Comparison of Various Weights, Capacities and Volumes.....	485

SEC. 28.—STRENGTH AND RESISTANCE OF MATERIALS.

I.—General Principles.

Stress.—Strain.—Modulus of Elasticity.....	486
--	-----

Elastic Limit.—Yield Point.—Ultimate Strength or Stress.....	487
Static Stress.—Repeated Stresses.—Alternating Stresses.....	487
Working Stress and Factor of Safety.....	487
Resilience or Work of Materials Under Stress—Formulas, Table.....	488
Effect of Sudden Loading, and Impact.....	489

II.—Tables of Strength of Materials.

A.—WOODS.

Compression (End) Tests of Timber, 12% and 15% Moisture.....	490
Strength Factors for Reducing Moisture from 15% to 12%.....	491
Compression (End) Tests of Green Timbers—Above 40% Moisture....	491
Bending Tests of Timber at Rupture.....	492
Bending Tests of Timber at Relative Elastic Limit.....	493
Compression Tests of Timber Across Grain.....	494
Shearing Tests of Timber With Grain.....	494
Relation Between Weight and Strength of Timber.....	494
Timber in Tension, Compression, Bearing, Bending and Shear.....	495
Remarks on Preceding Table.—Formula for Longitudinal Shear.....	496

B.—METALS.

Tension, Compression, Bending, Shearing, etc.....	496-507
Notes on Comparison of Aluminum and Copper in Electric Transmission	496
Notes on the Relative Conductivity of Silicon-Bronze Wire to Copper..	497
Standard Specifications for Gray Iron Castings.....	498
High Tensile Strength of Steel in Important Structures.....	499
Specifications for Structural Steel for Bridges.....	500
Specifications for Open-Hearth Boiler Plate and Rivet Steel.....	501
Specifications for Steel Rails, and Steel Castings.....	503
Specifications for Steel Axles.....	504
Specifications for Steel Forgings.....	505

C.—BUILDING STONES, CEMENTS, ETC.

Compression, Tension, Bending, etc.....	507-512
Tests of Bluestone and Brick; Rattler Test for Bricks.....	507
Tests of Cements; Natural and Portland Compared.....	508
Tests of Concrete; Formula Deduced from Tests.....	508
Modulus of Elasticity and Coefficient of Expansion of Concrete.....	510
Cinder Concrete—Watertown Arsenal Tests.....	510
Compressive Strength of Granite, Marble and Masonry.....	511
Compressive Strength of Sandstone, Slate and Terra Cotta.....	512

D.—MISCELLANEOUS MATERIALS.

Strength of Canvas, Cotton, Flax, Glass, Ice, etc.....	512
--	-----

III.—Heat Effects on Various Substances.

Definitions—A Gas, Liquid, Solid, Critical Point, Critical Temperature.	512
Definitions—Critical Pressure, Boiling Point, Latent Heat of Vaporiz'n.	513
Definitions—Melting Point, Latent Heat of Fusion.....	513
Liquefaction of Gases—Four Methods; Absolute Zero of Temperature..	513
Boiling Point, Freezing Point, etc., of Gases and Liquids, Table.....	514
Boiling Point of Substances at Atmospheric Pressure, Table.....	514
Melting Points of Various Substances, Table.....	515
Coefficients of Expansion—Formulas and Table.....	516

IV.—Frictional Resistance of Materials.

Coefficient of Friction of Revolving Journals.....	517
Friction of Plane Surfaces Which Have Been Some Time in Contact...	517
Friction of Plane Surfaces in Motion Upon Each Other.....	519
Friction of Journals in Motion Upon Their Pillows.....	520
Coefficients of Friction and Angles of Repose or Friction.....	521
Rolling Friction (Dry)—Formula.....	521

V.—Miscellaneous Data.

Crushing Tests of Brick and Terra Cotta Piers, Tables.....	522
The Effect of Fire on Building Materials.....	523
Gypsum as a Fireproofing Material.....	523
Some Tests of Old Timber, Compared With New.....	523

SEC. 29.—PROPERTIES AND TABLES OF PLANE SURFACES.

I.—Geometrical Figures.

Any Figure : Axis through <i>c.</i> of <i>g.</i> ; Axis at Base; Parallel Axis.....	524
Triangle : Axis through Center of Gravity.....	524
Triangle : Axis at Base; Axis through Apex.....	525

Triangle, Rectangle, Hollow Rectangle, Square, Hollow Square....	525
Parallelogram, Rhomboid.....	525
Square, Hollow Square, Trapezoid, Regular Hexagon.....	526
Hollow Hexagon, Regular Octagon, Hollow Octagon.....	527
Circle, Hollow C., Semicircle, Circular Sector, Circular Half-Segment ..	528
Ellipse, Hollow E., Parabolic Half-Segment, Parabolic Spandrel	529

2.—Skeleton Figures With Thin Lines.

Vertical Web Plate; Straight Line about Parallel Axis.....	529
Angle, Tee, Cross, H-Section, Rectangular Cell, Channel, I-Beam.....	530
I-Beam, Inclined Lines, Angles, Triangular Cell, Circular Cell.....	531
Circular and Semi-Circular Arcs—Five Cases.....	531
Corrugated Sheets—Cycloidal and Screw-Thread Shaped.....	532

3.—Block Shapes.

Flanges, Cross, I-Beam, Z-Bar, Tee, Angle, Channel.....	533
I-Beam, Channel, Z-Bar, Tee with Tapered Stem.....	534

4.—Rolled.

Moments of Inertia About Inclined Axis, Formulas.....	535
Moment of Inertia About Inclined Axis, Problem.....	537
Max. and Min. Values of I About Inclined Axis, Formulas.....	537
Properties of T-Beam; Properties of Channel.....	537
Properties of Tee, Z-Bar, Angle.....	538
Moments of Inertia of Rectangles, Table.....	539, 540

SEC. 30.—PROPERTIES AND TABLES OF STEEL SHAPES.

List of Tables and Relevant Tables in All Sections.....	541
Steel Rods, Square and Round—Weights and Areas, Table.....	542
Steel Plates—Weights and Areas, Table.....	544
Steel Angles, Unequal Legs—Properties of, Table.....	548
Steel Angles, Equal Legs—Properties of, Table.....	552
Steel I-Beams—Properties of, Table.....	554
Steel Channels—Properties of, Table.....	556
Steel Z-Bars—Properties of, Table.....	557
Steel T-Shapes—Properties of, Table.....	558
Steel Rail Sections—Dimensions and Properties, Table.....	560
References: Steel H-Shapes, Corrugated Sheetting, Memoranda.....	561

SEC. 31.—PROPERTIES AND TABLES OF BEAMS AND GIRDERS.

Working Stress, Load, Moment, Slope and Deflection of Beams—Formulas	562
Practical Examples in Use of Preceding Formulas.....	564
Span and Deflection for Plastered Ceiling—Examples.....	564
Longitudinal Shear in Beams—Formulas and Problem.....	565
Safe Uniform Loads on Rectangular Beams, Table.....	566
Examples in Use of Preceding Table.....	567
Steel Beam Box Girders—Properties of, Table, Problem.....	568, 569
Steel Plate-Girders, Complete—Properties of, Table.....	570, 571
Flange Angles of Plate-Girders—Properties of, Table.....	572-574
Web Plates of Plate-Girders—Properties of, Table.....	575-579
Flange Plates of Plate-Girders—Properties of, Table.....	580-582
Bethlehem Girder (Single I) Beams, Table.....	583
Bethlehem Special I-Beams, Table.....	584
Reinforced Concrete Beams—Working Stresses.....	585
Computing the Strength of Reinforced Concrete Beams.....	585
Various References—Concrete Beams and Slabs, etc.....	586

SEC. 32.—PROPERTIES AND TABLES OF COLUMNS.

General Stresses.—Shearing Effect.....	587
Notation for Column Formulas—Various End Conditions.....	587
Formulas—Short Strut—Eccentric Loading—Long Columns.....	588
Ritter's Formula for Columns.....	589
Author's Formula for Columns.....	590
Gordon's Formula for Columns.....	592
C. Shaler Smith's Formula for Wooden Columns.....	593
Straight-Line Column Formulas—Table.....	593
Safe Loads for Wooden Columns, Pin Bearing—Table.....	594
Steel Columns—Secondary Stresses—Useful Sections.....	596
Channel Columns—Table of Standard Dimensions.....	596
Ultimate Strength of Steel Columns—General Table.....	597
Z-Bar Columns, Without Side Plates—Table.....	598, 599

Z-Bar Columns (14-Inch), With Side Plates—Table.....	600
Channel Columns (6-Inch), With Flat Ends—Table.....	601
Channel Columns (8-Inch), With Flat Ends—Table.....	602
Channel Columns (10-Inch), With Flat Ends—Table.....	603
Phoenix Steel Columns—Table of Dimensions, Loads, etc.....	604
Cast Iron Columns, Rectangular and Round—Table of Strengths ..	606, 607
Rolled Steel H-Columns (8" to 14")—Tables.....	608
Reinforced Concrete Columns—Working Stresses.....	609
Carbon-Steel and Nickel-Steel Columns—Tests and Formulas.....	609
Tests of Plain and Reinforced Concrete Columns.....	610

SEC. 33.—STRUCTURAL DETAILS.

Rivets—Conventional Rivet Signs—Osborn Code.....	611
Rivets—Shearing and Bearing Values—Table.....	612
Problems in Riveted Joints.....	612
General Rivet Spacing, Clearances, etc.—Table.....	613
Rivet Gages for Standard Steel Shapes—Table.....	614
Standard Connection Angles for I-Beams and Channels.....	615
Weights and Dimensions of Rivets—Table.....	616
Riveted Joints—Kinds, and Table for Finding Net Areas.....	617
Standard Bolts for Fastenings; Standard Screw Threads, Table.....	618
Dimensions and Weights of Hot Pressed Nuts, Table.....	619
Bolts—Table of Dimensions for Heads, Nuts, etc.....	620
Weight of 100 Bolts with Square Heads and Nuts, Table.....	621
Weights of Nuts and Bolt Heads, Table.....	621
Lag Screws—Table of Weights—Use of.....	622
Wood Screws—Table of Sizes.....	622
Cast Iron Separators for I-Beams—Table and Remarks.....	623
Cast Iron Washers and Plate Washers—Table and Remarks.....	624
Steel Wire Nails, Miscellaneous—Weights and Dimensions, Table.....	625
Steel Wire Nails and Spikes, Standard—Tables and Remarks.....	626
Spikes and Nails; Tacks; Railroad Spikes;—Tables.....	627
Boat Spikes; Street Railway Spikes; Cut Nails and Spikes;—Tables..	628
Standard Pin-Nuts, with Weight of Pins—Table.....	629
Details of Bridge Pins, Cotter Pins, Pin-Nuts, Pilot-Nuts, etc.....	629
Pins—Bending Moments, and Bearing Value on Plates—Table.....	630
Eye Bars—Ordinary and Adjustable—Material to Form Head, etc....	631
Clevises—Table of Dimensions and Weights.....	632
Sleeve Nuts and Turnbuckles—Tables of Weights and Dimensions.....	633
Upset Screw Ends for Round and Square Bars, Table.....	634
Sleeve Nuts; Lateral Rods, Solid or Upset Eyes, Loop Welded Eyes, Det'l's	634
Segmental Rollers for Bridge Expansion—Formulas and Table.....	635
Howe Truss Brace Problem—Solution.....	635
Tables of Cubes and Squares—List of, and Uses.....	636
Finding Bending and Resisting Moments from Table of Squares.....	637
Finding Moments of Inertia from Table of Cubes.....	637
Solving Triangles from Table of Squares.....	638
Table of Cubes of Inches, 0" to 9", Advancing by 64ths and 32nds....	639
Tables of Cubes of Inches, 9" to 29", Advancing by 16ths.....	640
Table of Cubes of Inches, 29" to 109", Advancing by 8ths.....	641, 642
Table of Squares, 0' to 1', Advancing by 64ths of an Inch.....	643, 644
Table of Squares, 1' to 10', Advancing by 32nds of an Inch.....	645-650
Table of Squares, 10' to 52', Advancing by 16ths of an Inch.....	651-664
Cost of Shop Drawings for Structural Iron and Steel.....	665
Tests of Nickel-Steel Riveted Joints.....	665

SEC. 34.—METAL GAGES.

Standard Metal Gages—B. W. G., B. & S., etc.—Table.....	666
U. S. Standard Gage for Sheet and Plate Iron and Steel, Table.....	667

SEC. 35.—CORDAGE, WIRE AND CABLES.

Technical Cordage Terms—Make-Up (In Manufacture).....	668
Rope—Technical Terms in Manufacture and Use.....	668
Rope—Knots, Hitches, Bends, Splices, etc.....	668, 669
Manila Rope—Manufacture, Strength and Weight.....	669
Manila Rope—Weight and Strength—Working Load—Tables.....	670
Comparison of Wire Gages—B. W. G., B. & S., Edison—Tables.....	671
Table of Properties of Roebling Steel Wire—English and Metric.....	672
Wire Rope—Manufacture, Use, Strength, Lubrication.....	673

Roebbling Round Wire-Rope—Table or Properties.....	674
Wire Rope Fastenings—Details.....	675
Telephone Cable in St. Gothard Tunnel—Description.....	676

SEC. 36.—PIPES AND TUBES.

Wrought Iron Welded Steam, Gas and Water Pipe—Tables.....	677, 678
Lead and Tin Lined Lead Pipe and Tubing, Tables.....	679
Weight of Lead, Sheet Lead and Cast Tin.....	679
Spiral Riveted Steel Pipe and Specials, Table.....	680, 681
Spiral Riveted Steel Pipe Details.....	682

SEC. 37.—BRIDGES.

Economic Lengths of Spans for River Crossing, Formula.....	683
Economic Depth of Plate Girders and Trusses, Formulas.....	684
Estimating Weights of Bridges.....	685
Formula for Additional Length of Eye-Bars to Form Heads.....	686
Formulas for Weights of Steel Bridges and Trestles.....	686
Formula for Finding Bending Stresses in Eye-Bars.....	686

SEC. 38.—RAILROAD BRIDGES.

Moments and Shears—Beams or Girders—Distributed Loads.....	688
Easy Method of Drawing a Moment Parabola.....	688
Moments and Shears—Concentrated (Axle, Wheels, etc.) Loads.....	690
Engine Diagrams, Axle Loads, with Table.....	690
Typical Moment Diagram of Special Locomotive.....	691
Bending Moments and Shears from Special Locomotive, Table.....	692
Moments and Shears—Spans with Floorbeams.....	693
Concentrated Loads—Maximum Floorbeam Reactions.....	694
Concentrated Loads—Positions for Maximum Moment.....	695
Chord Stresses in Pratt Truss from Concentrated Loads, Problem.....	695
Chord Stresses in Warren Truss from Concentrated Loads.....	696
Concentrated Loads—Positions for Maximum Shear.....	696
Lateral Bracing—Wind and Curve Pressure.....	697
Portal and Intermediate Vertical Bracing, Formulas.....	698
General Specifications for Steel Railroad Bridges.....	699
General Description—Material, Types of Bridges, Clearance.....	699
Trusses, Girders, Floorbeams, Stringers, Wooden Floor, Guards.....	700
Loads—Dead Load, Live Load.....	700
Effect of Impact, Formula.—Engine Diagrams.....	701
Wind Pressure; Momentum of Train; Centrifugal Force.....	702
Proportion of Parts—Least Thickness of Material.....	702
Permissible Tensile and Compressive Stresses.....	702, 703
Alternate Stresses; Combined Stresses.....	704
Transverse Loading of Tension or Compression Members.....	704
Shearing and Bearing Stresses.....	704
Bending Stress on Pins.—Plate Girders.....	704
Provision for Future Increase of Live Load.....	705
Details of Construction—Camber; Adjustable Members.....	705
Truss Bridges; Lateral and Sway Bracing.....	705
Diagonal Bracing; Gusset Plates; Temperature.....	705
Bolsters and Expansion Rollers; Bed Plates.....	705
Rivets; Tie Plates; Lacing; Pin Plates.....	705, 706
Workmanship—Riveted Work; Planing and Reaming.....	706
Workmanship—Eye-Bars; Machine Work.....	706
Steel—Manufacture; Properties; Pins; Castings.....	706
Cooper's Standard Loading—Axle Loads—Table.....	707
Moments, Shears and Fl.-Bm. Reac.—Cooper's Loading—Table.....	708
Coefficients of Impact—Formula and Table.....	709
Permissible Compressive Stresses—Soft and Med. Steel—Table.....	710
Approx. Weight of Steel in Railroad Bridges—Formula, Tables.....	710
Plans and Details of Howe Truss.....	711
Reinforced Concrete Bridges.....	712
Safe Unit Stresses in Structural Timber, Table.....	713

SEC. 39.—ELECTRIC RAILWAY BRIDGES.

Typical Loadings—"L" and "K".....	716
Moments, Shears and Fl.-Bm. Reac.—"L 24" Loading—Table.....	717
Moments and Fl.-Bm. Reactions—"K 25" Loading—Table.....	718
Maximum End Shears from "K 25" Loading—Table.....	719

SEC. 40.—HIGHWAY BRIDGES.

Unit Stress Sheets for Various Types of Trusses—Tables.....	720-726
Calculation of Stresses by Graphics.....	725
Case of Cutting Four Active Members.....	726
Typical Loading for Highway Bridges—Table.....	727
Live-Load Data for Floor Systems and Spans Under 50 Ft.....	728
Maximum Moments and End Shears for "L" Loadings—Table.....	728
Uniform Live Loads for Trusses of Spans Over 50 Ft.—Table.....	729
Details of Combination Bridge, 230-Ft. Span.....	729-736
Nickel-Steel and Carbon-Steel Spans—Costs, Specifications—Table.....	737, 738
Reinforced Concrete Bridges—Cost Data.....	738, 739

SEC. 41.—CANTILEVER BRIDGES.

Reactions by Formulas and Influence Diagrams.....	740
Deck Cantilever Bridges; Camber.....	741

SEC. 42.—MOVABLE BRIDGES.

Types—Swing, Traversing, Bascule, Lift, Pontoon.....	742
Swing Bridges—Drawbridges—Rim-Bearing, Center-Bearing.....	742
Rim-Bearing Draw—Four Supports—Reactions—Formulas.....	743
Continuous Girder—Four Supports—Formulas.....	743
Rim-Bearing Draw—Four Supports—Reactions—Table.....	744
Rim-Bear'g Draw—Reactions and Moments for Balanced L'ds—Table.....	745
Calculation of 315 Ft. Drawbridge—Graphical Solution.....	746
Center-Bearing Draw—Three Supports—Mom. and Reac.—Formulas.....	746
Continuous Girder—Three Supports—Formulas.....	746
Center-Bearing Draw—Three Supports—Mom. and Reac.—Table.....	747
Deck Drawbridge—Center-Bearing—Hints for Calculation.....	748
Formulas for Weight of Steel in Swing Bridges.....	748
Counterweight Jack-Knife Drawbridge.....	748
Steel Bascule Bridges.....	749

SEC. 43.—SUSPENSION BRIDGES.

Theoretical—Curve of Main Cables—The Parabolic Cable.....	750
The Catenarian Cable—Formulas and Tables.....	751, 752
Linear or Skeleton Arch.—Graphical Solution of Catenary.....	753
The Transformed Catenary.....	753
Practical—Cables or Chains; Towers and Backstays.....	754
Anchorage.—Cable Wrappings.....	755
Manhattan Bridge Details—Description—Live Loads.....	756
Manhattan Bridge—Specifications—Material, Allowable Stresses.....	758
Longitudinal Section of Anchorage.....	759
Weight of Materials in Manhattan Bridge, Table.....	760
Economic Considerations.....	760

SEC. 44.—ARCHES.

Theoretical Forms; Transformed-Catenary Arch.....	761
Masonry Arches; Parts of an Arch; Kinds of Arches.....	763
Further Classification of Arches; Brick Arches.....	764
Masonry Arch, a Statically Indeterminate Structure.....	764
Curve of Intrados, 764; Thickness of Arch Ring, Formulas.....	765
Crown Thickness for Masonry Arches, Table.....	766
Springing Thickness for Masonry Arches, Table.....	767
Forces Acting on a Masonry Arch.....	767
Calculation of Arches—Theoretical Hints.....	768-770
Centers for Arches; Parts of the Arch Center.....	770
Centers for Arches—Loads, 771; Types of Centers.....	773
Striking the Center; Camber of Center.....	773
Some Notable Arches That Have Been Built, Table.....	774
Some Typical Modern Arches, Table.....	778
Concrete Culverts—Quantities.....	782
Steel Arches—No-Hinged and Two-Hinged—Position Lines.....	782
Plan of 4-Track, Railroad, 2-Hinged Steel Arch Bridge.....	783
Three-Hinged Arch—Position Line.....	783
Cost of Reinforced Concrete Bridges.....	784

SEC. 45.—TRESTLES.

File Trestles, Timber Trestles—Plans and Dimensions.....	787
File and Timber Trestles—A., T. & S. F. R. R. Plan.....	790

Wooden Stringers—Allowable Bending Moments, Table.....	791
Steel Trestles.—Elevated Railroad Trestles.....	791, 792
Reinforced Concrete Trestles.....	792
Cost of Railroad Trestles—Timbers, Steel, and Rein.-Conc.....	793
Reinforced Concrete Trestles Actually Built, Described.....	793

SEC. 46.—ROOFS.

Wind Pressure—Velocities; Direct Pressure, Formulas.....	794
Direct Normal Wind Pressures, Table.....	795
Effect of Wind Suction or Tension.....	795
Normal and Component Wind Pressures, Formulas.....	795
Normal Wind Pressures on Inclined Surfaces, Table.....	976
Wind Pressure on Pitched Roofs, Table.....	797
Wind Pressures in Open Sheds, and on Cylinders and Spheres.....	797
Snow Loads on Roofs—Latitude-Altitude Diagram.....	797, 798
Roof Coverings.....	798
Shingle Roofing; Weight of Shingles Laid on Roofs, Table.....	799
Slate Roofing; Number of Slates Laid on Roofs, Table.....	799
Weight of Slate; Total Weight per Square of Roof;—Tables.....	799, 800
Tile Roofing—Kinds and Specifications.....	800
Tin Roofing—Roofing Tin—Plates.....	800
Steel Sheet Roofing; Corrugated Steel R., Formula; Tar-Gravel Roof..	801
Cement-Gravel R., Asphalt-Gravel R.; Slag R.; Patented R.....	802
Weight of Roofing Materials, Table.....	802
Common Types of Roof Trusses; Stress Diagrams.....	803, 804
Unit Stresses in Pratt Roof Trusses, Table.....	804
Unit Deductions for Half Truss (Lean-to).....	805
Unit Stresses in Fan and Pink Trusses, Table.....	805
Unit Deductions for Half Truss (Lean-to).....	806
Design for Combination Roof Trusses—Spacing of Jack-Rafters.....	806
Design of Sheathing and Jack-Rafters.....	807
Design of Purlins and Trusses.....	808
Table of Stresses, and Stress Sheet, of Roof Truss.....	809
Details of Roof-Truss Design—Chord Splice, Chord Block, Keys, etc....	810
Weight of Steel Construction in Roofs, Formulas.....	810
Steel Roofs—Approximate Weight of Trusses and Purlins—Table.....	811

SEC. 47.—BUILDINGS.

Plastering.—Lathing.—Partitions.....	812
Wooden Partitions; Hollow Tile Partitions; Other Partitions.....	813
Expanded Metal Partitions and Lathes.....	814
Floors, Ceilings, etc.—Live and Dead Loads.....	814
Live Loads—Minimum for Floors and Roofs—Ten Cities—Table.....	815
Maximum Live Load Possible from People.....	815
Loads from Safes, with Problem.....	816, 817
Table of Weights and Dimensions of Heavy Safes.....	816
Examples of Floor and Ceiling Construction.....	817, 818
NEW YORK CITY Building Code—Digest.....	819-823
Quality of Materials.—Excavations and Foundations.....	819
Wooden Beams, Girders and Columns.—Fireproof Buildings.....	819
Iron and Steel Construction.—Floor Loads.....	820
Calculations.—Strength of Materials.....	821
Reinforced Concrete Construction.....	822, 823
Allowable Stresses for Steel and Concrete, Table.....	823
CHICAGO Building Ordinance—Digest.....	823, 824
Reinforced Concrete—Ratio of Moduli of Elasticity.....	823
Reinforced Concrete—Adhesion—Bond.....	824
PHILADELPHIA Building Laws and Ordinances—Digest.....	824, 825
Live Loads for Floors and Roofs.....	824
Calculations.—Ultimate and Working Stresses.....	824
Allowable Pressures.—Reinforced Concrete Construction.....	825
BOSTON Building Law—Digest.....	825-827
Materials—Allowable Fiber Stresses.....	825
Concrete and Reinforced Concrete Construction.....	826
BUFFALO Building Laws—Digest.....	828, 829
Concrete and Reinforced Concrete Construction.....	828
Hollow Concrete Blocks.....	829
Reinforced Concrete Building—Formulas for Unit Stresses.....	831
Reinforced Concrete—Standard Building Regulations.....	831

Cutting Structural Steel Work with Oxy-Acetylene Flame	833
Wind Loads on Mill Buildings.....	833

SEC. 48.—RETAINING WALLS.

Theory of Earth Pressure, 835; Rankine's Theory.....	839
Cubic Yards of Masonry in Retaining Walls, Table	841
Comparative Sections of Thirty Retaining Walls, Table.....	842

SEC. 49.—DAMS.

Common Fixed Types, Described.....	844
Stability of Gravity Dams.—Hydrostatic Pressure	845
Center of Pressure—Formulas	846
Center of Gravity of Trapezoid—Analytically and Graphically.....	847
The Triangular Dam	847
Pressure on Foundations, Formulas.....	848
Factor of Safety Against Overturning.—Shear.....	850
Pressure on Foundations, Table.....	851
Masonry Gravity Dam—Calculations and Design.....	852-854
Effect of Profile on Gravity Dams.....	854
Dimensions and Quantities for Masonry Dams, Tables.....	855, 856
Dimensions and Quantities for Rock-Fill Dams, Table.....	857
Dimensions and Quantities for Earth Dams, Table.....	858
High Masonry Dams—Table of Dimensions.....	859
Comparative Cross-Sections of High Earth Dams.....	859
Rubble-Concrete Dam—Cyclopean Masonry.....	860
The Eastwood Multiple-Arch Dam, Described.....	860

SEC. 50.—FOUNDATIONS.

Foundation Beds—Rock, Gravel, etc.....	863
Actual Bearing Pressures on Bed Rock, Table.....	864
Actual Bearing Pressures on Sand, Table.....	864
Actual Bearing Pressures on Gravel, Table.....	865
Actual Bearing Pressures on Clay and Sand, Table.....	865
Soils—Practical Test, Selection of Site, Examination.....	865
Borings in Soil.—Estimating Loads on Foundations.....	866
Bearing Power of Soils, from Various City Codes—Table.....	867
Foundations for Machines, Dynamos, etc.....	867
Types of Foundation Footings.....	867
Steel I-Beam Footing for Independent Piers.....	868
Coffer-Dams—Types Described.....	868
Sheet Piling—Types—Timber and Steel.....	869, 870
Pile Foundations—Supporting Power of Piles.....	871
Pile-Driving Formulas for Drop Hammer and Steam Hammer.....	871
Safe Bearing Power of Piles, Table.....	872
The Drop Hammer and Steam Hammer, Described.....	872
Pile Drivers—Derrick, Power and Water-Jet.....	873
Pile Shoes; Pile Foundations; Splicing Piles; Cutting Off Piles.....	874
Piles—Dead-Men Piles; Iron Piles; Screw Piles; Disk Piles.....	874
Piles—Sand Piles; Concrete Piles; Water-Jet Concrete Piles.....	875
Piles—Metal Shell Concrete Piles; Reinforced Concrete Piles.....	875
Open Caissons	876
Crib Piers; Pile Piers; Tubular Piers.....	877
Cushing Piers.....	878
Platform Cylinder Piers.—Pneumatic Cylinder Piers and Process.....	879
Pneumatic Foundations—Caisson and Crib.....	880
Coffer-Dam.—Freezing Process.....	882
Masonry Piers, Design.....	888
Contents of Piers by Prismoidal Formula.....	889

SEC. 51.—WHARVES, PIERS AND DOCKS.

Definitions.—Foundations.....	892
Pierhead and Bulkhead Lines.—Construction Methods.....	892
Piers.—Ferry Slips and Bridge Aprons.....	893
Plans of Ferry Crib, Dolphin and Bridge.....	894-899
Reinforced Concrete Wharf Construction.....	900

SEC. 52.—BREAKWATERS.

Types of Breakwaters.....	901
Quantities and Cost per Lin. Ft. of Breakwater, Table.....	902

Statistics of Notable Breakwaters, Table.....	903
Materials for Concrete in Buffalo Breakwater.....	904
SEC. 53.—JETTIES.	
Jetty Construction.—Fascines.....	905
SEC. 54.—EARTHWORK.	
Uncertain Cost.—Kind and Quality of Material.....	906
Approved Methods of Handling.—Clearing and Grubbing.....	906
Loosening Earth.—Loading and Conveying.....	907
Superintendence.—Labor.....	908
Earth Embankment.—Shrinkage of Earth.....	909
Experiments on Shrinkage of Earth.....	913
Shrinkage in Volume and Vertical Shrinkage.....	915
Performance of Work—Methods and Costs.....	915
Diamond Drill Borings, Deep Waterways Survey, Table.....	917
Railroad Grading with Wheeled Scrapers, Costs.....	917
Trenching and Backfilling for Sewer Pipe, Costs.....	918
Earthwork Classification—Solid Rock, Loose Rock, etc.....	919
References to Earthwork and Especially to Shrinkage.....	920
Machine for Excavation in Frozen Ground, Cost Data.....	921
SEC. 55.—ROCK EXCAVATION.	
Open Rock Cuts—Drills, Drilling, etc.....	922
Trenching in Rock, Methods; Chicago Drainage Canal.....	923
Chicago Drainage Canal—Methods and Costs, Tables.....	924
Performance of Work—Methods and Costs.....	925
Use of Well Driller for Drilling Blasting Holes, Costs.....	926
SEC. 56.—DREDGING.	
Methods of Measuring Material.—Dredges, Types.....	927
Elevator (Bucket) Dredge.—Hydraulic Dredge.....	928
Blasting Under Water—Dredging Detroit River.....	929
Detroit River—Dredging, Drilling, Scows—Cost Tables.....	930
Gold Dredging in California.....	930, 939
Performance of Work—Methods and Costs.....	931
Large Elevator Dredge for Work in Boston Harbor, Described.....	932
SEC. 57.—TUNNELING.	
Definitions.—Kinds of Tunnels.....	933
Methods of Tunneling—Open Cut—"Heading" vs. "Drift".....	933
Drilling and Blasting.—Timbering.—Lining.....	934
Alignment and Grade.—Ventilation.....	935
Shield Method.—Dredging Method.—Caisson Method.....	936
Performance of Work—Methods and Costs.....	937
Some Notable Tunnels that Have Been Built, Data.....	937
Some Detail Tunnel Costs, Los Angeles Aqueduct.....	939
SEC. 58.—SURVEYING, MAPPING AND LEVELING.	
Care of Instruments.—To Adjust the Level.....	941
To Adjust the Transit, 942, The Solar Attachment.....	944
The Solar Instrument—Description and Use.....	944
To Adjust the Solar Attachment.....	947
Solar Observations with Transit Alone—Calculations.....	947
To Determine the Meridian from the North Star.....	948
Polar Distance of Polaris for Lat. 0°, and Any Latitude.....	949
Azimuth of Polaris at Elongation Jan. 1, Table.....	950
Observations of Polaris at Elongation, or at Any Hour Angle.....	951
Time—Civil, Astronomical and Railway.....	952
Local Mean Time of Upper Culmination of Polaris, Table.....	953
Azimuth of Polaris for Use of Land Surveyors, Table.....	954
Polaris Tables for the Year 1912.....	955a-955f
Tapes.—Temperature Corrections, Table.....	956
Sag and Stretch of Tapes—To Correct.....	957
Table of Equivalents of Feet and Chains.....	958
Methods of Plotting Angles.—Table of Chords.....	959
Farm Surveying—Equipment and Method—Adjustment of the Traverse.....	964
Office Plan and Finished Map.—City Lot Surveying.....	966
Government Land Surveying.—Acts of Congress.....	967

General Rules from the Foregoing Acts.....	968
To Restore Lost or Obliterated Corners—Rules.....	969
Rules for Subdivision of Sections.....	970
Useful Tables in Public Land Surveys—Meridians and Base Lines.....	971
Azimuths of the Secant, and Offsets to the Parallel—Table.....	973
Azimuths of the Tangent to the Parallel, Table.....	974
Offsets from Tangent to Parallel, Table.....	975
Correction of Randoms, Table.....	976
Convergency of Meridians—Table and Examples.....	977, 978
Lengths of a Degree of Latitude to Minutes, Table.....	979
Lengths of a Degree of Longitude to Minutes, Table.....	981
The Stadia.—Stadia Reduction Table.....	983, 984
Leveling Correction for Curvature and Refraction.....	987
Correction for Earth's Curvature, and Refraction—Table.....	988
Allowable Errors in Leveling, Table and Formula.....	989
Description of Four Stadia Surveys and Their Cost.....	990

SEC. 59.—RAILROADS.

A.—General Discussion.

Existing Mileage, etc.—Economic Principles.....	991
Tractive Force of a Locomotive—Grades—Formulas.....	992
Tractive Force of Engines on Various Grades, Table.....	994
Allowable Expense for Grade Reduction.....	995
Cost of Haul on Various Grades, Table.....	996
Economic Considerations of Curvature and Distance.....	997

B.—Reconnaissance Survey.

Aneroid Barometer—Formula, etc.....	998
Table of Barometric Elevations.—Barometric Correction Table.....	999

C.—Preliminary Survey.

Field Operations—Locating Engineer and Transitman.....	1000
Table of Grades—Ft. per 100 Ft. to Ft. per Mile, Equivalents.....	1001
Table of Stations Corresponding to Distance in Miles.....	1001
Table of Grades—Angles for Rates of Grades, Equivalents.....	1002
Table of Grades—Ft. per Mile to Ft. per 100 Ft., Equivalents.....	1003
Table of Grades—Angles for Ft. per Mile, Equivalents.....	1003
Duties of Levelman and Topographer.—Mapping.....	1004

D.—Location Survey.

Profiles and Grades.....	1004
Parabolic Vertical Curves.—Horizontal Circular Curves.....	1005
Table of Radii of Curves—English and Metric.....	1007
Table of Tangents and Externals to 1° Curve—English and Metric.....	1009
Minutes and Seconds to Decimals of Degree or Hour, Table.....	1010
Various Problems in Simple Curves.—Compound Curves.....	1011
Solution of Compound Curve Problems—Table of Formulas.....	1012
Reversed Curves—Formulas.....	1012
Cubic Parabola.—Spiral Curve.—Easement Curves.....	1013

E.—Right of Way.

Filing the Location.....	1013
Purchase and Condemnation.....	1014
Table for Finding Widths of R.-of-W. for Cuts and Fills.....	1014
Tables for Finding Acreage of Right of Way.....	1015

F.—Construction.

Methods of Calculation of Earthwork.....	1016
List and Description of Earthwork Tables, with Page No.....	1017
Multiplication Tables for Earthwork Calculation.....	1018-1020
Slope-Staking and Earthwork Computation.....	1055
The Prismoidal Formula and Prismoidal Correction Formula.....	1055
Tables of Prismoidal Corrections.....	1056-1058
Earthwork Correction for Curvature.—Haul.—Roadbed.....	1059
Rails and Fastenings—Standards.....	1060
Standard Dimensions of Rails and Fastenings, Table.....	1061
Weight of Rails Reduced to Tons per Mile of Track, Table.....	1063
Middle Ordinates for Curving Rails, Formulas.....	1063
Middle Ordinates for Curving Rails, Tables.....	1064-1067
Chord Lengths of Curved Rails, Tables.....	1066, 1067
To Find the Degree of Curve of Laid Track, Formulas.....	1066
Track Spikes—Table.—Rail Joints.....	1068

Formula for Thickness of Shims in Tracklaying.....	1069
Cross Ties.—Table of Cubic Feet in Wooden Ties.....	1069
Table of Feet Board Measure in Wooden Ties.....	1070
Bills of Switch Ties for Nos. 6 and 8 Frogs, Tables.....	1070
Cross Ties—Best Kinds, Life, and Time to Cut.....	1071
Tie Plates—Types, and Advantages.—Rail Braces.....	1071
Steel Ties.—Concrete Steel Ties.....	1072
Ballast—Kinds, and Amount Required.....	1073
Track Gage.—Wheel Gage, M. C. B. Standard.....	1073
Increase of Gage for Various Curves, Table.....	1073
Gages and Half-Gages of Track, with Log Values—Table.....	1074
Various Track Gages in Use.—Best Standard Gage.....	1074
Turnouts and Switches.—Frogs.—Frog Numbers.....	1075
Manganese Steel Frogs.—Spring Rail Frogs.....	1075
Properties of Frog Angles and Half Frog Angles, Table.....	1076
Movable-Point Frogs.....	1076
Crossing Frogs.—Stub Switches.....	1077
Table for Laying Out Switches in the Field.....	1078
Table of Theoretical or Stub Switches.....	1079
Table of Radii of Theoretical Turnout Curves.....	1081
Table of Theoretical Switches for Any Gage.....	1082
Turnout Curves for Stub Switches, Formulas.....	1083
Formulas for Double Turnout Curves.....	1084
Turnout Curves from Curved Main Track, Formulas.....	1084
Split Switches.....	1084
Turnouts for Split Switches and Spring Frogs, Table.....	1085
Three-Throw Turnouts, Split Switches—Table.....	1086
Turnouts from Straight Track, Split Switches—Table.....	1087
Formulas for Split Switches.....	1087
Wharton Switch.....	1088
Ladder Tracks—Spacing of Frogs—Table.....	1089
Crossovers—Spacing of Frogs—Table.....	1090
Standards of Track Construction on American Railways.....	1093
Street Railway Track Construction and Paving.....	1094

SEC. 60—HIGHWAYS.

A.—Traction.

Power of a Horse.—Effect of Road Surfaces on Traction.....	1097
Effect of Grades on Traction—Formulas, Tests, Problem.....	1097

B.—Roads and Streets.

Definitions.—Dirt Roads.—Corduoy Roads.....	1098
Plank Roads.—Gravel Roads and Walks.....	1098
Broken-Stone Pavement.—Hydraulic Cement Pavement.....	1099
Cement Sidewalks.....	1099
Wood-Block Pavements.—Cobblestone Pavement.....	1099
Belgian Block Pavement.—Granite Block Pavement.....	1100
Brick Pavement.—Asphalt Pavement.....	1100
Asphalt Paving Blocks.—Bituminous-Rock Pavement.....	1100

C.—Pavement Specifications.

Allegheny County, Pa.:—Road Specifications.....	1101
Boston:—Granite Block Pavement—Brick Sidewalk.....	1102
Wood Block Pavement—Brick Sidewalk.....	1103
Asphalt Pavement.—Bitulithic Pavement.....	1104, 1105
Macadam Roadway—Crushed Stone Sidewalk.....	1105
The Proper Construction of Brick Pavements.—(W. P. Blair).....	1106
Cincinnati:—Boulder Pavement.....	1107
Detroit:—General.—Brick Pavement, Concrete Foundations.....	1108, 1109
Sheet Asphalt Pavement on Concrete Foundations.....	1110
Cedar Block Pavement on Concrete Foundations.....	1110
Easton, Pa.:—Macadam and Telford Roads.....	1111
Concrete Curbs, Gutters and Sidewalks.....	1111
Reinforced Concrete Foundations—Reference.....	1111
El Paso, Tex.:—Petrolithic Pavement.....	1111
Los Angeles:—Gravelled Streets.....	1111
Bituminized Brick Gutters.....	1111
Maryland State Highway:—Macadam Construction.....	1111
Nat'l Association Cement Users:—Portland Cement Sidewalk.....	1111

Manhattan (N. Y. City):—Granite Block Pavement.....	
Wood Block Pavement.....	
Richmond (N. Y. City):—Iron Slag Block Pavement.....	
Vitrified Brick Pavement.....	
Asphalt Block Pavement.—Curb on Concrete Foundation.....	
Richmond, Ind.:—Street Crowning, Table.....	
Syracuse, N. Y.:—General.—Vitrified Brick Pavement.....	
Sandstone Block Pavement.....	
Asphalt Sheet Pavement.....	
Cresoted Wood Block Pavement.—Bitulithic Pavement.....	
Toronto, Ont.:—Grading.....	
Cedar Block Pavement.—Concrete.—Asphalt Pavement.....	
Brick Pavement.—Macadam Roadway.—Concrete Walk.....	

D.—Care of Road Surfaces.

Dust Preventives:—Classification.....	
Tars, their Manufacture and Properties—Coal Tars.....	
Water-Gas Tar.—Composition of Tars.....	
Application of Tars to Finished Road Surfaces.....	
Use of Tar in Road Construction.....	
Oils, their Classification and Properties.....	
Application of Heavy Oils to Surfaces, and Roads.....	
Specifications for Coal Tars.....	
Experiments with Dust Preventives:—.....	
Tar Experiments—Miscellaneous and Cost Data, Tables.....	
Cost of Applying Calcium Chloride.....	
Rock Asphalt and Oil Experiments—Cost Data.....	1138
Asphalt and Bituminous Rock Deposits of the U. S.....	

E.—Miscellaneous.

Paving a Country Road with Brick.....	
Inverted Macadam Road Construction.....	
Vitrified Clay Curbing for Streets and Roads.....	
Sidewalk and Paving Practice in Chicago, Cost Data.....	
Experience in Dust Suppression on N. J. Roads, Cost Data.....	
Tests of Various Road Surfacing Materials, Table.....	

SEC. 61.—HYDROSTATICS.

Definitions.—Atmospheric Pressure.—Air.—Water.....	
Hydrostatic Pressure—Units and Formulas.....	
Hydrostatic Head and Pressure, Equivalents (1-10), Tables.....	
Head in Feet for Given Pressures per Square Inch, Table.....	
Pressure for Square Inch for Given Heads in Feet, Table.....	
Pressure for Square Foot for Given Heads in Feet, Table.....	
Center of Pressure on Submerged Surfaces, Formulas.....	
Center of Pressure on Orifices, Weirs, etc., Table.....	
Pressure on Pipes, Tanks, etc.—Flotation.—Buoyancy.....	
Metacenter.—Laws of Equilibrium.....	

SEC. 62.—HYDRAULICS.

Definitions.—Theory of Flow—Formulas.....	
Velocity and Discharge, Formulas.....	1155
Theoretic Velocities for Various Heads, Table.....	(283)
Areas of Pipes in Sq. Ft. for Diameter in Ft. and Ins., Table.....	
Velocity in Pipes or Varying Cross-Section, Formulas.....	
Losses During Flow Through Pipes, Formulas.....	
Hydraulic Grade Line.—Velocity of Approach.....	
Total Head.—Loss of Head due to Friction.....	
Hydraulic Notation and Formulas.....	
Economic Sections of Conduits—Maximum Velocity.....	
Chey's Hydraulic Formula.—Kutter's Formula.....	
Values of n (and c) in Kutter's Formula.....	1168
Coefficients c in Kutter's Formula, Table.....	1170
Practical Examples in Use of Kutter's Formula.....	
The Venturi Meter.....	
Meter Register; Manometer; Piezometer Tubes.....	
Orifices, Tubes, Nozzles and Jets—Formulas and Tables.....	
Weirs—Standard Weir—Theoretic Discharge, Formulas.....	
Francis' Weir Formulas.....	
Bazin's Weir Formula; and Value of m , Table.....	1178

Fteley and Stearns' Weir Formulas.....	1180
Parmley's Weir Formula; and Values of C' and K , Tables.....	1180
Triangular and Trapezoidal Weirs.....	1181
The Submerged Weir:—.....	1181
Fteley and Stearns' Formula; and Values of m , Table.....	1181
Herschel's Formula; and Values of c , Table.....	1181, 1182
Hydraulic Measurements—Tank, Venturi, Weir, etc.....	1182
Hook Gage.—Pilot Tube Meter.—Floats.....	1183
Current Meters—Rating and Use.—Meter Register.....	1185, 1186
Depth of Thread of Mean Velocity in Rivers.....	1187
Values of n in Kutter's Formula Determined for Earth Canals.....	1187
Durability of Wood Stave Pipe Actually Laid.....	1187
Values of c and n in Kutter's Formula—Experiments, Table.....	1188
Bazin's Hydraulic Formula.....	1189
Friction of Air in Small Pipes, Formula.....	1189

SEC. 63.—WATER SUPPLY.

Source.—Rainfall—Distribution.—Artesian Nomenclature.....	1190
Average Monthly Precipitation in the U. S., Table.....	1191
Percentage of Rainfall to Average Rainfall, Table.....	1195
High Intensities of Rainfall, Notation.....	1195
Maximum Intensity of Downpour, Formulas.—Rain Gage.....	1196
Maximum Rates of Rainfall by Preceding Formulas, Table.....	1197
Runoff.—Measuring Stream Discharge.....	1197
Runoff Formulas.—Effect of Slope.....	1198
Evaporation from Ice, Snow, Water Surface, etc.....	1199
Monthly Evaporation from Water Surfaces in the U. S., Table.....	1199
Seepage and Evaporation in Canals, etc.....	1200

SEC. 64.—WATER WORKS.

A.—Consumption of Water.

Water Meters, and Waste of Water.....	1202
Population in 17 Cities of the U. S., from 1850 to 1906—Table.....	1202
Water Consumption in 17 Cities of the U. S., from 1850 to 1906—Tab.....	1203

B.—Purification of Water.

Screening.—Sedimentation.—Slow Sand Filtration.....	1204
Rapid Sand Filtration—Mechanical.—Copper Sulphate.....	1204

C.—Reservoirs.

Storage Reservoirs.—Distributing Reservoirs.....	1205
Reservoir Linings.—Stand Pipes—Formulas for Design.....	1206

D.—Conduits.

Canals.—Flumes.—Bored Wooden Pipe.—Salt Glazed Pipe.....	1207
Masonry Aqueducts—Reinforced Concrete.....	1208
Bored Wooden Pipe, Banded.—Wood Stave Pipe, Details.....	1208
Wood Stave Pipe and Details, Table.....	1210–1213
Notes on Preceding Table—Bands and Shoes.....	1214
Discharge in Gallons through Wood Stave Pipe, Table.....	1214
Cast Iron Pipe.....	1214
Formulas for Designing Cast Iron Pipe.....	1215
Kinds of Pipe Joints.—Bell and Spigot Joint Pipe.....	1215
Cast Iron B. and S. Pipe, with Lead and Hemp Data—Table.....	1216
Friction Heads in Clean Cast Iron Pipe, Table.....	1217, 1218
Examples in Use of Preceding Table.....	1219
Notes on Pipe Laying and Taking Up Laid Pipe.....	1219
Weights and Dimensions of C. I. Pipe and Specials, Tables.....	1219–1267
Straight Cast Iron Pipe.....	1220, 1222, 1223, 1243–1246
Bells of Special Castings.....	1221, 1223
Cast Iron Pipe Curves.....	1224, 1248, 1249
Cast Iron Pipe Branches—L's, T's, Crosses.....	1225–1227, 1250–1254
Cast Iron Pipe Branches—Y's.....	1227, 1228, 1255, 1256
Cast Iron Pipe Hydrant Branches.....	1229
Cast Iron Pipe Blow-Off Branches.....	1230, 1231, 1257, 1258
Cast Iron Pipe Sleeves.....	1232, 1265
Cast Iron Pipe Increasers and Reducers.....	1233, 1259–1264
Cast Iron Pipe Caps.....	1234, 1266
Cast Iron Pipe Lugs.....	1247
Cast Iron Pipe Offsets.....	1235, 1249

Cast Iron Pipe Plugs.....	1234, 1267
Cast Iron Manhole Pipe.....	1232, 1259
Standard Specifications for Cast Iron Pipe.....	1239
Turned and Bored Joint Pipe.....	1235
Flanged Joint Pipe.....	1235
Standard Flange Pipe, Table.....	1236
Flexible Joint Pipe.....	1238
Wrought Iron Pipe.—Steel Pipe.....	1268
Riveted Steel Pipe—Formulas and Design.....	1268
Steel Pipe Rivet Table.—Locking Bar Joint Pipe.....	1269
Lap-Welded Pipe.—Spiral Riveted Pipe.....	1269
Pressure Pipe Attachments.....	1269
Sluice-Gate, Stand and Wheel.—Air Relief Valves.....	1270
Metropolitan Air Valves, Table.—Standpipes.—Gate Valves.....	1271
Ludlow Bronze Mounted Double Gate Valves—Nomenclature.....	1272
Weights and Dimensions of M. W. W. Gate Valves, Table.....	1273
Dimensions of Ludlow Double Gate Valves, Table.....	1247, 1275
Weights of Ludlow Gates and Valves, Table.....	1276-1279
Blow-offs.—Special Pipe Connections.....	1280

E.—Distributing System.

Cast Iron Pipe.—Lead-Melting Furnace.—Matheson Pipe.....	1280
Matheson Pipe and Specials, Tables.....	1281
Converse Pipe, Table.—Pipe Dipping Tank.....	1282
Tapping Machines—Mueller.....	1283
Black or Galvanized Pipe—Dimensions and Weights—Table.....	1284
Discharge in Gallons through Small Pipes, Table.....	1284
Gate Valves—Chapman and Eddy Types.....	1285
Ludlow Double Gate Valves, Dimensions—Table.....	1286, 1287
Gate Boxes.—Weight of Ludlow Gate Boxes, Table.....	1288
Check Valves.—Pressure Relief Valves.—Hydrants.....	1288
Hydrants—Nomenclature of Parts.....	1289
Weights of Ludlow Hydrants, Table.....	1290

F.—Miscellaneous Data.

Costs of Slow and Rapid Sand Filtration.....	1291
Efficiencies of Riveted Pipe Joints.....	1291
Water Purification in Reservoirs, Cost Data.....	1292
Steel Pipes for Water Works—Economics.....	1292
Pneumatic Calking of Mains with Lead Wool.....	1293
Waterproofing the New Ulm Reservoir.....	1293

SEC. 65.—SANITATION.

The Disposal of Refuse.—House Drainage.....	1295
Cesspools.—Sewers—Size and Grade.....	1296
Values of r , $\sqrt{r}$ and $\alpha\sqrt{r}$ for Circular Sections, Table.....	1297
Factors for Using Preceding Table for Other Sections, Table.....	1298
Examples in Use of Preceding Table.....	1298
Velocities of Circular Brick Sewers, Table.....	1299
Properties of Circular Conduits or Sewers, Formulas.....	1300
Properties of Catenary Conduits or Sewers, Formulas.....	1301
Properties of Basket-Handle Conduits or Sewers, Formulas.....	1302
Properties of Gothic Conduits or Sewers, Formulas.....	1303
Properties of Egg-Shaped Conduits or Sewers, Formulas.....	1304
Velocities in Egg-Shaped Sewers, Table.....	1305
Examples in Use of Preceding Table.....	1306
Thickness of Brick Sewer Walls, Formula.—Sewer Foundations.....	1306
References to Illustrated Sewer Construction.....	1306
Sewer Pipe.—Weight and Cost of Sewer and Culvert Pipe, Tables.....	1307
Sewers and their Classification.....	1307
Location of Sewers.—Manholes.—Catch Basins.....	1308
Quantities in Mortar Mix for Sewer Joints, Table.....	1309
The Wear of Sewer Inverts.....	1310
Sulphur and Sand for Sewer Pipe Joints, Table.....	1310
Cost of 66-Inch Sewer at Gary, Indiana.....	1310

SEC. 66.—IRRIGATION.

General Discussion.—Irrigation Units.....	1313
Miner's Inch—Equivalents of Discharge—Table.....	1313
Equivalents of Discharge of One Cu. Ft. per Sec., Table.....	1314

Units of Volume—Acre-Foot and Acre-Inch.....	1314
Rates of Discharge for One Acre-Foot per Day, Table.....	1314
Rates of Discharge for One Acre-Foot per Month, Table.....	1315
Duty of Water in Irrigation.....	1315
Duty of Water—Measurements at Different Points—Tables.....	1316
Duty of Water—Losses in Main Canal Included—Table.....	1316
Duration of Irrigation Period on Some Canals, Table.....	1316
Duty of One Cu. Ft. per Sec., and Inches in 10 days—Table.....	1317
Canals.—Data on Some Perennial Canals, Table.....	1317
Conduits and Flumes.....	1317
Field Location of Irrigation Ditches and Canals.....	1318
Cost Data on Drainage of Irrigated Lands.....	1319

SEC. 67.—WATERWAYS.

Suez Canal.—Cronstadt and St. Petersburg Canal.....	1320
Corinth Canal.—Manchester Ship Canal.....	1320
Traffic Data on Suez Canal, Table.....	1321
Kaiser Wilhelm Canal.—Elbe and Trave Canal.....	1322
Welland Canal.—Sault Ste. Marie Canals.....	1322
Canadian Canal Systems.—Lake Borgue Canal.....	1323
Chicago Drainage Canal.—Proposed Am. Isthmian Canal.....	1324
Distance Data via Panama and Nicaragua Routes.....	1328
Harlem River Canal.—Cost of Maintenance of Canals.....	1329
Principal Commercial Canals of the U. S.—Table.....	1329, 1330

SEC. 68.—WATER POWER.

Definitions and Formulas.—Economic Design of Penstock.....	1332
Horsepower per Cubic Foot of Flow per Second, Table.....	1333
Horsepower—Hours from Storage of One Million Cu. Ft., Table.....	1334
Horsepower—Hours from Storage of One Acre-Foot, Table.....	1335
Water Motors—Wheels—Current, Undershot, Breast, Overshot.....	1336
Impulse Water Wheels.....	1336
Single Nozzle Pelton Water Wheel Data, Table.....	1338
Quintex Nozzle Pelton Water Wheel Data, Table.....	1342
Turbine Water Wheels—Nomenclature of Terms.....	1342
Losses of Energy in Turbines; Efficiencies of Turbines.....	1343
Theoretic Horsepower of Turbines.—Transmission of Power.....	1344
Important Designs for Reference.....	1345

SEC. 69.—STEAM AND GAS POWER.

A.—Heat.

Matter and Energy; Kinds, Forms and Transformation of Energy.....	1346
Thermal Energy.—First Law of Thermodynamics.....	1347
Thermal Units—British, French, British-French.....	1347
Mechanical Equivalent of Heat, <i>J</i>	1347
Thermal Units—Equivalents (1-10), Mechanical Work—Table.....	1348
British Thermal Units, Power and Work—Equivalents (1-9)—Table.....	1349
Examples in Use of Preceding Table.....	1350

B.—Fuel.

Heating Power of Fuels—Methods of Determination.....	1350
Chemical Analysis.—Coals Classified by Carbon and Volatiles, Table.....	1350
Proximate Analysis and Heating Values of U. S. Coals, Table.....	1351
Ultimate Analysis of Fuel, Defined.....	1351
Chemical Analysis of Several Kinds of Solid Fuels, Table.....	1352
Calculation of Heat of Combustion—Formulas; Calorimeter.....	1352
Practical Boiler Tests—Coal as Fuel—Table.....	1353

C.—Steam.

General Discussion—Kinds of Steam.....	1354
Superheated Steam and Saturated Steam, Formulas.....	1355
Saturated Steam Tables, Described; Heat of Vaporization, Formula.....	1356
Saturated Steam Tables—Old.....	1357, 1358
Saturated Steam Tables—Revised.....	1359, 1360
Flow of Steam Through Pipes—Formula and Table.....	1361
Steam Boilers—Efficiency and Commercial Horsepower Rating.....	1361
Consumption of Coal per Boiler Horsepower—Hour.....	1362
Kinds of Steam Boilers; Boiler Settings.....	1362

---------------	-----------

INDEX.....	1539-1611
------------	-----------

INTRODUCTION.

General Discussion.—The young engineer or student should realize that, although engineering is not an exact science itself, it is, in its entire field, founded on the exact sciences, supplemented with experimental data. As he becomes more proficient in his work he will discern certain broad, underlying *principles* which he will begin to use instead of mere *methods* or rules, formerly employed. It should be his aim to master these principles thoroughly.

MATHEMATICS.

The various branches of mathematics as taught in our common schools are based on methods of operation rather than on mathematical principles, for when viewed from the latter standpoint they overlap each other to such an extent that the dividing lines are not always clearly marked. For instance, the science of *number, space, quantity, position, motion, mass, force* and *inertia* cannot be taught in logical sequence from out text-books as now arranged.

In view of the above, and of the fact that an attempt has been made in the body of this work to classify the subject matter of mathematics under the usual headings—Arithmetic, Algebra, Geometry, etc.,—it is deemed pertinent here to introduce a discussion of the more abstract science of *number, space, quantity*, etc., as preliminary to the main text, recognizing here none of the divisions, as such, which are contained in the latter.

NUMBER.*

The science of Arithmetic involves the principles of Algebra; these principles in turn having been deduced from the theory of number, and so on.

Number is independent of the order of counting.
—In counting any number of things, the counting of the last one contains the numeral word which designates the total number, no matter in what order they are counted. In the illustration, for example, there are five dots in each case.

Fig. 1.

A Sum is independent of the order of adding.
In finding the sum of two or more groups of things, it matters not in what order they are added; as 3 added to 5 equals 5 added to 3, equals 8; or, $3 + 5 = 5 + 3 = 8$. 3 plus 5 plus 4 = $5 + 3 + 4 = 4 + 5 + 3$; etc., = 12.

Fig. 2.

Using *shorthand* characters or letters to represent numbers the same law holds true: as, $a + b = b + a$; $a + b + c = b + a + c$; etc.

A Product is independent of the order of multiplying.—

4 3's = 4 times 3 = $4 \times 3 = 12$; or, $a \times b = ab = 12$.
3 4's = 3 times 4 = $3 \times 4 = 12$; or, $b \times a = ba = 12$.
Similarly, $4 \times 3 \times 5 = (4 \times 3) \times 5 = 4 \times (3 \times 5) = 3 \times (4 \times 5) = 60$. And using shorthand, in which the letter $a = 4$, $b = 3$, and $c = 5$: $a \times b \times c = abc = acb = bac = bca = cab = cba = 60$.

Note the 6 ($1 \times 2 \times 3$) different ways of arranging the 3 letters.

$a = 4$			
1	2	3	4
2			
3			

Fig. 3.

* See, also, Clifford's "Common Sense of the Exact Sciences."

A Product is independent of the parting of its factors.—Thus, $7 \times 5 = (7 \times 3) + (7 \times 2) = 21 + 14 = 35$, or, by shorthand, $ab = ae + af = a(e+f)$. Again, $7 \times 5 = (6+1)(3+2) = 6(3+2) + 1 \times (3+2) = 30 + 5 = 35$ or, $ab = (c+d) \times (e+f) = c(e+f) + d(e+f) = e(c+d) + f(c+d)$.

A Power is independent of the parting of the index.—

The *first power* of a number is the number itself; as $a^1 = a$.

The *square* of $5 = 5^2 = 5 \times 5$; of $a = a^2 = aa$; in which 2 is the *index*.

The *cube* of $7 = 7^3 = 7^1 \times 7^2 = 7^{1+2} = 7 \times 7^2 = 7^{1+1+1} = 7 \times 7 \times 7$; of $b = b^3 = bb^2 = bbb$.

The *fourth power* of $a = a^4 = a^{3+1} = a^{2+2} = a^2 a^2 = a^2 a^2 = a^{\frac{4}{2}} = \sqrt{a^4}$.

The *fifth power* of $2 = 2^5 = 2 \times 2 \times 2 \times 2 \times 2 = 2(2 \times 2 \times 2 \times 2) = (2 \times 2)(2 \times 2 \times 2)$ or, $2^5 = 2^{1+4} = 2^{2+3} = 2 \times 2^4 = 2^2 \times 2^3$.

The *square root* of the *fifth power* of $4 = \sqrt{4^5} = \sqrt{4^{4+1}} = \sqrt{4^4 \times 4} = \sqrt{4^4} \times \sqrt{4} = 4^2 \sqrt{4} = 16\sqrt{4} = 16 \times 2 = 32$; or $\sqrt{4^5} = 4^{\frac{5}{2}} = 4^{2\frac{1}{2}} = 4^2 \times 4^{\frac{1}{2}} = 4 \times 4^{\frac{1}{2}} = 4 \times 4 \times 4^{\frac{1}{2}} = 32$; or, $\sqrt{4^5} = \sqrt{4^2 \times 4^3} = \sqrt{4^2 \times 4^2 \times 4} = \sqrt{4^2} \times \sqrt{4} = 4 \times 4 \times 2 = 32$.

From the above it will be seen that $a^0 = 1$, for $a = a^{n-n} = \frac{a^n}{a^n} = 1$.

Square of $(a+1)$ is a special case of $(a+b)^2$.
 $(4+1)^2 = (4+1)(4+1) = 4(4+1) + 1(4+1) = 16 + 4 + 4 + 1 = 25$.

$(a+1)^2 = (a+1)(a+1) = a(a+1) + 1(a+1) = a^2 + 2a + 1$.

$(a+b)^2 = (a+b)(a+b) = a(a+b) + b(a+b) = a^2 + 2ab + b^2$.

Again: $(a-1)^2 = a^2 - 2a + 1$; and $(a-b)^2 = a^2 - 2ab + b^2$.

Practical application: $(21)^2 = (20+1)^2 = (20)^2 + 2 \times 20 + 1 = 400 + 40 + 1 = 441$;

also, $(19)^2 = (20-1)^2 = (20)^2 - (2 \times 20) + 1 = 400 - 40 + 1 = 361$.

Note.—By making b *extremely small* compared with a , in the case of $(a+b)^2$, it will be seen that the third term b^2 , as b approach zero, can be omitted, as it will be the square of an infinitely small decimal or fraction. Hence, the limit of $(a+b)^2$ as b approaches zero, is $a^2 + 2ab$, or, in other words, the actual *increase* of $(a+b)^2$ over a^2 , where b is infinitely small, is $(a^2 + 2ab) - a^2 = 2ab$.

This is an elementary principle of the *Differential Calculus*—the method of limits.

$(a^2-1) = (a+1)(a-1)$ is a special case of $(a^2-b^2) = (a+b)(a-b)$.

$(4^2-1) = (4+1)(4-1) = 4(4-1) + 1(4-1) = 4 \times 3 + 1 \times 3 = 12 + 3 = 15$.

$a^2-1 = (a+1)(a-1) = a(a-1) + 1(a-1) = a^2 - a + a - 1 = a^2 - 1$.

$a^2-b^2 = (a+b)(a-b) = a(a-b) + b(a-b) = a^2 - ab + ba - b^2 = a^2 - b^2$.

Practical application: $41 \times 39 = (40+1)(40-1) = 40^2 - 1 = 1600 - 1 = 1599$.

From $a^2 = (a+1)(a-1) + 1$, we have $39^2 = 40 \times 38 + 1 = 1520 + 1 = 1521$.

Fig. 6.

SPACE.

An Object is composed of layers and bounded by a surface.—The *surface* of an object has a definite area, but as it has no thickness, in itself, it occupies no space. On the other hand, the layers composing the object, no matter how thin we may assume them theoretically, must occupy space and have thickness. In theory we assume such shapes as cones, cylinders, spheres, etc., to be composed of an *infinite* number of layers of an infinitesimal thickness, t .

A *Surface* is an area with or without lineal boundary.—The surface of the Earth, of a chair, of a cube, or of any *whole* object can have no lineal boundary; but the surface of *part* of an object, as of a continent, of one face of a cube, or of the top of a table is bounded by lines along the edges of the surface. Neither the surface nor its bounding lines can have thickness nor occupy space.

Fig. 7.

The surface of an object is its *shape*.

A *Line* is a boundary, division, or an intersection, of surfaces.—The *boundary* of a surface is a curved or broken line of definite length, and *continuous*; that is, without terminal points. A good illustration of this is a traverse survey, as around a farm. If the field notes do not "close" they are made to close by "adjustment."

A *plane* surface can be divided by a *straight* line, of definite length only, that is, with terminal points at its boundaries; but it can be divided also by a *curved* or broken continuous line, as for instance by a circle, entirely within its boundaries.

Fig. 8.

Fig. 9.

Fig. 10.

Fig. 11.

The intersections of the surfaces of the *cube* furnish the *right angle* and the *square*; the intersections of the surfaces of the *wedge* furnish the *triangle* and the *rectangle*; and, similarly, the *pyramid*, in its various forms, furnishes the numerous *polygons*.

By *cutting surfaces*, the *cone* furnishes the *point*, p , the *straight line*, ps , the *triangle*, ps , the *circle*, C , the *ellipse*, E , the *parabola*, P , the *hyperbola*, H , etc. Its properties embrace such a wide range in Analytic Geometry that the subject is often termed *Conic Sections*.

The boundary of a surface is its *shape*.

QUANTITY.

Quantity is a summation of units, of one, two or three dimensions.—

The *first* involves continuity, length, or number; as time, angles, weights, lengths, money and numerals.

The *second* involves length and breadth, or area; as surface measures.

The *third* involves length, breadth and depth, or contents; as measures of volume.

Area is a summation of one or more products of two factors each.—If we divide the surface of the right triangle, Fig. 12, into *extremely thin* strips of length y , and thickness t , and then move the apex to one side, as in Fig. 13, allowing the thin strips to slide on one another, their ends will still form straight lines from the apex, a , to the base of the triangle, and its height and area will remain the same. The area of the triangle is the summation of the areas ($y \times t$) of all the thin strips. The above illustrates two principles, namely, simple proportion and the equation of the straight line, as ; thus—

Fig. 12.

Fig. 13.

Simple proportion: $\frac{y}{x} = \frac{b}{h}$.

Equation of the straight line, as : $y = \frac{b}{h}x$.

The straight line is sometimes called a curve of the first degree.

The same law holds true in the case of any figure, as Fig. 14 where the boundary line as is a curve of the second degree; for it is necessary only to find the equation of the curve in terms of x and y so that for each value of x we may know the value of y . In either case we derive the area from the summation of all the infinitesimal strips yt between the limits $x=h$ and $x=0$. This may be performed accurately by the method of the Calculus, by assuming an infinite number of infinitesimal strips.

Fig. 14.

If we consider Fig. 12 to be an elastic layer of definite thickness, having the surface as shown, and apply a lateral pressure at the apex, a , to change its shape to Fig. 13, we conceive in Mechanics the terms *force*, *elasticity*, *stress*, *strain* and *shear*.

Length is a summation of the square roots of the sums of squares.—

It is an elementary problem to prove that the square H (hypotenuse²) is equal to the square B (base²) plus the square P (perpendicular²), by the proposition that H is composed of two rectangles B' and P' equal in area to B and P , respectively. From this principle the length of any curve may be obtained by the summation of its infinitesimal parts.

Thus, required (Fig. 16) to find the length S of the curve ac between the limits $x=c'$ and $x=a'$. We have here to find the summation of the infinitesimal tangent lengths ds in terms of dy and dx for every change of position of the tangent as the values of x and y change. It is evident that each infinitesimal length $ds = \sqrt{dx^2 + dy^2}$, hence if we find the values of dx^2 and dy^2 from the equation of the curve, by the Calculus, we can get the value of ds in general terms. It only remains to find the summation of all the values of ds , that is, S , and this may be obtained by integration, subtracting the result obtained by making $x=a'$, from the result obtained by making $x=c'$.

Fig. 15.

Fig. 16.

The ratio of the circumference of a circle to its diameter = 3.141592+, called π .

Volume is a summation of layers; or area times thickness.—If a beam of homogeneous material and of rectangular cross-section be loaded so

* The general equation of the straight line is $y = mx + c$, in which m is the tangent of the angle, and c is a constant. In the above, $c=0$.

that it deflects, as in Fig. 17, there will be a plane $s-s$ through the middle of the beam which will not change from its original length; that is, there will be no stretching or shortening of the fibers along this plane, which may be called the *neutral axis* of the beam. If now the beam be turned

Fig. 17.

on its side and again deflected, a new plane, $s'-s'$, at right angle to the first, will become a new neutral axis. In either case the fibres at the top of the beam will be compressed and the fibres at the bottom of the beam stretched, equally. Also, the stretching or compression of any fibre in the beam will be proportional to its distance from the neutral axis. In other words, while the beam loses in volume above the neutral axis it gains an equal amount below. The intersection of the neutral axes will also be found to be at the center of gravity, *c. g.*, of the section. The center of gravity may be defined as the point of intersection of all possible neutral axes, for no matter which way the beam may rest, on its corner or otherwise, the neutral axis will pass through the center of gravity of the section.

The center of gravity of any *regular* section, as a square, rectangle, parallelogram, equilateral triangle, circle or regular polygon is in the center of the figure. (Fig. 18.)

The center of gravity of a triangular section is one-third the height from either base. (Fig. 19.)

These principles furnish the rules for finding the contents of the cylinder, circular ring, cone, paraboloid, ellipsoid, or any similarly curved bodies.*

Consider any section lying wholly on one side of the axis of revolution, or center of curvature; multiply the area of the section by the distance traversed by its center of gravity. The product will be the volume of revolution of that section.

For example, the volume of a cone is equal to the area of the triangle of revolution $\times \frac{1}{3}$ the base $\times 2\pi$

$$= \frac{bh}{2} \times \frac{b}{3} \times 2\pi = \frac{\pi b^2 h}{3} = \frac{h}{3} \times \text{area of base. (Fig. 20.)}$$

Fig. 19.

Fig. 20.

POSITION.

The *Relative Position* of an object may be determined by *one, two or three* quantities, according as it is on a known *line, surface* or *in space*. The third dimension problem can be reduced to the second by passing a known *surface* or *plane* through the point in space; and this can be reduced to the first by passing a known *line* through the point on the surface or plane. A distance along the line, measured to the object in question, will fix its exact position.

The Position of a Point on a Plane.—

The *polar co-ordinates*, angle α and distance D , locate the point P from A . Polar co-ordinates may be reduced to *rectangular co-ordinates*, x and y , Fig. 21.

Fig. 21.

Fig. 22.

* See also Pappus's Theorems for surfaces and solids, page 243.

A point P , Fig. 22, may be located from a fixed point A by a distance D , and from a fixed line $Y-Y$ by a distance x . If D and x are allowed to increase and decrease with constant ratio, the point P will trace (1) the parabola, if the ratio of D to x is unity; (2) the hyperbola, if the ratio of D to x is greater than unity; and (3) the ellipse, if the ratio of D to x is less than unity.

Fig. 23.

Fig. 24.

A point P , Fig. 23, may be located from two fixed points: A , by distance D , and B , by distance d . If the ratio of D to d is allowed to increase and decrease, but so their sum will remain constant, the point P will trace an ellipse.

The results of experiments are conveniently platted on cross-section paper, and a curve drawn as nearly regular as possible through the average position of the points. The curve then serves as a formula for future use.

Fig. 25.

If the curve is of the second degree it can be represented by a straight line if logarithmic cross-section paper, Fig. 25, is used. Hydraulic formulas and experiments are often platted on this kind of paper, for simplicity.

MOTION.

A man starts to row a boat, at a constant rate of speed, directly across the stream from *A* to *B*, not allowing for any current. On reaching the east bank he finds he has landed at *D*. If the current was uniform in all parts of the stream his course was the straight line *AoD*, and his motion down stream uniform in passing from the west to the east bank. If the current was very strong at the west bank and gradually lessened toward the east bank his course was the line *AcD* and his motion down stream a retarded one—uniformly retarded if the current at any point was directly proportional to its distance from the east bank. If the current gradually increased toward the east bank his course was the line *AbD* and his motion down stream an accelerated one—uniformly accelerated if the current at any point was directional proportional to its distance from the west bank.

Fig. 26.

The *average velocity* of the (surface of the) stream is the same for all three cases above cited if the boat lands at the same point, *D*.

Uniform velocity or motion may be represented by a straight line, i. e., curve of the first degree; uniformly accelerated or retarded velocity or motion, by a curve of the second degree.

The *acceleration* per second of time due to the gravity of the earth on any body falling in *vacuo* is practically constant. It is designated by the letter *g*, and its value is about 32.16 ft. per sec. It varies somewhat with the elevation above sea level and with the latitude of the place.

MASS (MATTER), FORCE AND INERTIA.

These are convenient terms used in Applied Mechanics to express certain co-relative ideas.

We may consider *mass* as matter, or that property which cannot be destroyed, because matter is indestructible, although the body of which it is composed may change its form or apparently disappear. Mass is proportional to weight, and the unit of weight is one pound. The mass

of a body is its weight, *W*, divided by gravity acceleration, *g*, as $M = \frac{W}{g}$; or, the mass of a body is measured by a force, *F*, which will produce an acceleration, *a*, as $M = \frac{F}{a}$. The acceleration in either case is the velocity attained at the end of the first second of time.

Force is a shorthand expression of stating the value of one mass acting on another, by pressure or impact. Force = mass $\times$ acceleration, $F = Ma$. Its unit is one pound.

Inertia is a negative term implying inherent inactivity in a relative manner: the tendency which a body has to continue doing what it is already doing—if at rest to *remain* at rest, and if in motion to *continue* in motion in the same direction and at the same velocity.

EXPERIMENTATION.

Several years ago the late Professor Joseph L. LeConte, in a very elaborate scientific discussion, "proved conclusively" that the heavier-than-air flying-machine was an absolute impossibility; and yet, today, aerial flights in such machines are attracting but passing interest.

Our college professors are daily teaching the maxim: "There is no conflict between theory and practice." This should be restated as follows: "There can be no conflict between correct theory and perfect practice, but neither can always be attained." The theory of Professor LeConte was incorrect—but nevertheless a theory—and the first experiments in flying, by Octave Chanute, were simply imperfect ones.

Joseph H. Choate, the able jurist, in an address before a society of engineers, a few years ago, exposed himself to criticism in stating that engineering was an exact science—a statement that is very far from the truth.

The great advance in the whole field of engineering—quite phenomenal during the past decade, especially—is due almost wholly to experimental work, scientifically conducted.

Management.

Scientific management is becoming a potent factor in the industrial world, and is destined to possess an increasing sphere of influence in the future. It simply means *intelligent cooperation*: distinctly opposed to the old system of bossism, which is more or less militant and invites toadyism—a qualification distasteful to every honest workman.

SIGNS AND ABBREVIATIONS.

Common Abbreviations.—The following abbreviations, and others not listed here, are used constantly throughout this volume in order to conserve space. In general, they appear in the text after the full word has been used so there can be no doubt as to the meaning:

abut	—abutment.	covers	—co-versed sine.
accel	—acceleration.		—(hyp — perp) + hyp.
ans	—answer.	exsec	—exsecant.
approx	—approximate.		—(hyp — base) + base.
cen	—center.	coexsec	—co-exsecant.
circum	—circumference.		—(hyp — perp) + perp
diag	—diagonal.	sec, s.	—seconds.
diam	—diameter.	min, m.	—minutes.
dist	—distance.	hrs, h.	—hours.
grav	—gravity.	d.	—days.
hd	—head.	mos.	—months.
hor	—horizontal.	yrs.	—years.
ht	—height.	e. g.	—for instance.
hyp, hypoth	—hypothénuse.	i. e.	—that is.
hyp log	—hyperbolic log.	etc.	—and so forth.
log	—logarithm.		—et. cetera.
perp	—perpendicular.	c. g.	—center of gravity.
pres	—pressure.	ins.	—inches.
pt	—point.	ft.	—feet.
rad	—radius.	yds.	—yards.
tang	—tangent.	lbs.	—pounds.
vel, veloc	—velocity.	pts.	—pints.
vert	—vertical.	qts.	—quarts.
vol	—volume.	gals.	—gallons.
wrt	—wrought.	bu.	—bushels.
wt	—weight.	bbls.	—barrels.
sin	—sine — perp + hyp.	lin.	—lineal.
cos	—cosine — base + hyp.	sq.	—square.
tan	—tangent — perp + base.	cu.	—cubic.
cot, cotan	—cotangent.	B. M.	—board measure.
	—base + perp.	M., B. M.	—thousand ft. B. M.
sec	—secant.	H. P.	—horse-power.
	—hyp + base.	A. W. G.	—American wire gauge.
csc, cosec	—cosecant.	B. W. G.	—Birmingham W. G.
	—hyp + perp.	r. p. s.	—revolutions per sec.
vers	—versed sine.	r. p. m.	—revolutions per min.
	—(hyp — base) + hyp.		

Greek Alphabet.—Greek letters are used in the sciences to designate certain properties, as angles, latitude, temperature, etc.

English Equivalents.	Greek Letters.			Used to designate.
	Name.	Capital	Small	
A	Alpha	$\mathbf{A}$	α	Angles and coefficients.
B	Beta	$\mathbf{B}$	β	Angles and coefficients.
G	Gamma	$\mathbf{\Gamma}$	γ	Angles, coefficients, and specific gravity.
D	Delta	$\mathbf{\Delta}$	δ	Angles, coefficients, deflection, variation and density.
$\bar{\text{E}}$	Epsilon	$\mathbf{E}$	ϵ	Eccentricity; base of natural logarithms = 2.7182818; strain.
Z	Zeta	$\mathbf{Z}$	ζ	Coefficients, co-ordinates.
$\bar{\text{E}}$	Eta	$\mathbf{H}$	η	Coefficients.
Th	Theta	$\mathbf{\Theta}$	θ, ϑ	Angles and coefficients.
I	Iota	$\mathbf{I}$	ι	
K	Kappa	$\mathbf{K}$	κ	Coefficients.
L	Lambda	$\mathbf{\Lambda}$	λ	Latitude, angles and coefficients.
M	Mu	$\mathbf{M}$	μ	Angles and co-efficients.
N	Nu	$\mathbf{N}$	ν	
X	Xi	$\mathbf{\Xi}$	ξ	Coefficients, co-ordinates.
$\bar{\text{O}}$	Omicron	$\mathbf{O}$	$\omicron$	
P	Pi	$\mathbf{\Pi}$	π	Π signifies continued product, as $\Pi 3 = 1 \times 2 \times 3$. $\pi = 3.14159+$ = ratio of circum to dia. = 180° of arc.
R	Rho	$\mathbf{P}$	ρ	Rad of gyration; rad of curvature; ratio.
S	Sigma	$\mathbf{\Sigma}$	σ, ς	Σ signifies summation; as ΣW means the summation of all the weights W', W'', W''' , etc., in any system. In the Calculus it is replaced by the symbol $\int$. σ is used as a coefficient; stress.
T	Tau	$\mathbf{T}$	τ	Coefficients; temperature, time.
U, Y	Upsilon	$\mathbf{\Upsilon}$	υ	
Ph	Phi	$\mathbf{\Phi}$	ϕ	Angles and coefficients.
Ch	Chi	$\mathbf{\chi}$	χ	
Ps	Psi	$\mathbf{\Psi}$	ψ	
$\bar{\text{O}}$	Omega	$\mathbf{\Omega}$	ω	Coefficients; angular velocities.

MATHEMATICAL SYMBOLS.

- a, b, c , --- Represent known or constant quantities.
 --- x, y, z , Represent unknown or variable quantities.
 = Equals, is equal to.
 + Plus, as $3+2=5$; positive, as $+\frac{1}{2}=+.5$; extension, as $\frac{1}{2}= .14285+$.
 - Minus, as $5-3=2$; negative, as $-\frac{1}{2}=-.5$; contraction, as $\frac{1}{2}= .17-$.
 $\pm$ Plus or minus, as $\sqrt{4}=\pm 2$.
 $\mp$ Minus or plus.
 $\times$ Times, multiplied by; as $3 \times 2=6$; $a \times b=a.b=ab$.
 $a.b = a \times b=ab$.
 + Divided by; as $8+2=4$; $8:2=4$; $8/2=4$; $\frac{8}{2}=4$.
 $\frac{a}{b}$ Divided by.
 a/b Divided by.

: :: : Proportion; as 2:3::4:6; means $\frac{4}{6}$; reads "as 2 is to 3 so is 4 to 6."

4.3 = 4 $\frac{3}{10}$ = 4 $\frac{30}{100}$, etc.

> Is greater than, as 4 > 3; reads "4 is greater than 3."

< Is less than, as 3 < 4; reads "3 is less than 4."

≥ Is equal to or greater than; as, $a \geq 4$.

≤ Is equal to or less than; as, $4 \leq a$.

∴ Therefore, hence.

∵ Because.

∞ Infinity; as, $\frac{a}{0} = \infty$.

α Is proportional to, varies directly with; also, angle alpha.

| Bar

— Vinculum

() Parenthesis

[] Bracket

{ } Brace

Abbreviation; denote that the quantities covered or enclosed must be "taken together."

$$\begin{aligned} \overline{a+b} \times c &= c(a+b) = ac + ab. \\ 2(a(b+c)+x) &= 2a(b+c) + 2x. \\ a \{ 2(a(b+c)+x)+d \} &= 2a[a(b+c)+x]+ad \\ &= 2a^2(b+c) + 2ax + ad \\ &= 2a^2b + 2a^2c + 2ax + ad. \end{aligned}$$

✓ Radical sign, square root. Thus $\sqrt{a} = \sqrt[2]{a} = a^{\frac{1}{2}} = \frac{1}{a^{-\frac{1}{2}}}$.

∛ Cube root.

√ⁿ n^{th} root.

a^2 The square or second power of a , as $a \times a$, or aa .

x^n The n^{th} power of x . $x^n = \frac{1}{x^{-n}}$; $x^1 = x$; $x^0 = 1$.

a — d Continuation. Thus, a, b, c, d . (Either dots or dashes may be used.)

a', k'', x''' Primes, to distinguish letters; as a —prime, k —2—prime or k —second, x —3—prime or x —third.

x_1, a_2, k_4 Subs, to distinguish letters; x sub 1, a sub 2, k sub 4.

∨ Inverted caret indicates repeating decimal; as, $0.016\overline{6} = 0.0166666\text{-----}$.

#— Number, as #2 = number 2.

—# Pound, or pounds, as 4# = 4 pounds or 4 lbs. in weight.

6'—3" Feet and inches (linear measure); as 6 feet 3 inches, or 6 ft. 3 ins.

0°—18'—15" Degrees, minutes and seconds (of arc); as 0 deg., 18 min., 15 sec. or 18m. 15s.

○ Round, diameter. 6° = 6 ft. diameter = 6' dia. 3° = 3 ins. diameter = 3" dia.

□ Square. 2° = 2 ft. sq.; 3° = 3 ins. sq. 4° = 4 sq. ft.; 9° = 9 sq. ins.

⊠ Cube. 2° = 2 ft. cubed; 4° = 4 ins. cubed. 27° = 27 cubic ft.

∠ Angle; ∠ angles.

⊥ Right angle.

⊥ Perpendicular to.

∥ Parallel with.

◎ Circle.

△ Triangle.

▵ Right angle triangle.

□ Square.

▭ Rectangle.

▭ Parallelogram.

$$\pi \text{ Pi} = 3.1416 = \frac{\text{circumference}}{\text{diameter}} \text{ of circle; or, } = 180^\circ \text{ of arc.}$$

$$\frac{180^\circ}{\pi} = 57.2958^\circ \text{ nearly.}$$

e = Base of Napierian, hyperbolic, or natural logarithms = 2.7182818+.

$\sin a$ Sine of the angle a .

$\sin^{-1} a$ Inverse on anti-sine of a ; the angle whose sine is a . It is *not* $= \frac{1}{\sin a}$; see below.

$$\sin a^{-1} = (\sin a)^{-1} = \frac{1}{\sin a}.$$

d Differential (in Calculus); $d(x^2) = 2xdx$.

Σ Sigma, summation.

Δ Delta, difference; usually considered as a very small quantity.

$\int$ Integral (in Calculus); the reverse of differentiation; $\int 2xdx = x^2$

$\int_k^h$ Intergral between limits h and k ; $\int_{x=k}^{x=h} 2xdx = h^2 - k^2$.

MECHANICAL SYMBOLS.

L or l = length.

M or m = mass.

T or t = time.

v = velocity.

a = acceleration, $a = \frac{F}{M}$.

g = gravity acceleration,
 $= \frac{W}{M} = 32.16 \text{ ft. per sec.}$
 per sec.

W or w = work, or weight.

P = power.

F = force.

ft.-lbs. = foot-pounds.

I = moment of inertia.

E = modulus of elasticity.

D = diameter.

r = radius.

H. P. = horse-power.

B. H. P. = brake horse-power.

I. H. P. = indicated horse-power.

M. E. P. = mean effective pressure.

r. p. m. = revolutions per minute.

C. G. S. = centimeter-gram-seconds (system).

A. W. G. = American wire gauge.

B. W. G. = Birmingham wire gauge.

B. T. U. = British thermal unit
 = pound-degree-Fahr.

cal. = calorie (French).

= kilogram-degree-Cent.

lb.-cal. = pound-calorie,
 = pound-degree-Cent.

ELECTRICAL SYMBOLS.

E. E. M. F. = electro-motive force.

P. D. = potential difference.

C = current.

R = resistance.

ρ = specific resistance.

Q = quantity.

K = capacity.

L = inductance.

A. M. = ampere meter.

V. M. = volt meter.

F. M. = field magnet.

$+$ = positive pole.

$-$ = negative pole.

V = volt, potential.

Amp. = ampere.

Ω = megohm.

B. A. U. = British Association units.

mfd = microfarad.

h., hy. = Henry.

J = Joule.

K. W. = kilowatt.

$\sim$ = complete period
 (alt. current).

$\bigcirc$ = dynamo.

$\text{---} \square \text{---}$ = battery.

Galvanometer.

Ammeter.

Voltmeter.

Wattmeter.

ELECTRICAL UNITS

Name.	Symbol.	Unit of	How Obtained.	CGS*	Equivalent.
Ohm.....	R	Resistance....	The electrical resistance of a column of mercury 106 centimeters long and of 1 square millimeter section.	10 ⁹	1 true ohm = 1.0112 British Association ohms.
Ampere.....	C	Current.....	Is that current of electricity that decomposes .00009324 gramme of water per second.	10 ¹	Deposits 1.118 milligrams of silver per second.
Volt.....	E	Electromotive force....	One ampere of current passing through a substance having 1 ohm of resistance = 1 volt.	10 ⁸	.926 of a standard Daniel Cell.
Coulomb.....	Q	Quantity....	A current of 1 ampere during 1 second of time.	10 ¹	Deposits 1.118 milligrams of silver.
Farad.....	K	Capacity.....	The capacity that a current of 1 ampere for 1 second (= 1 coulomb) charges it to potential of 1 volt.	10 ⁹	2.5 knots of D. U. S. cable.
Microfarad....	"		1 millionth of farad.	10 ¹⁵	
Watt.....	Pw.	Power.....	Power of 1 ampere current passing through resistance of 1 ohm.	10 ⁷	.0013405 (or $\frac{1}{746}$) of a horse power.
Joule.....	W. j.	Work.....	Is the work done by 1 watt of electrical power in 1 second.	10 ⁷	.238 unit of heat (Therm.)

* C. G. S. = Electro-magnetic units.

MAGNETIC AND ELECTROMAGNETIC UNITS.

	Magnetic Units.	Dimensions.		Electromagnetic Units.	Dimensions.
m {Strength of pole Quantity of mag- netism}	$-\sqrt{\text{force} \times (\text{distance})^3}$	$M^{\frac{1}{2}} L^{\frac{3}{2}} T^{-1}$	C	Current (strength)	$-\left\{ \begin{array}{l} \text{intensity of field} \times \\ \text{length} \end{array} \right\} =$
V {Magnetic potential Intensity of field}	$-\text{work} + \text{strength of pole}$ $-\text{force} + \text{strength of pole}$	$M^{\frac{1}{2}} L^{\frac{3}{2}} T^{-1}$ $M^{\frac{1}{2}} L^{-\frac{1}{2}} T^{-1}$	Q V E	Quantity Potential Electromotive-force}	$-\text{current} \times \text{time}$ $-\text{work} + \text{quantity}$ $-\text{E. M. F.} + \text{current}$

M. F.} + \text{current} \\ \text{per sec.} \end{array} \right\} =$

MAGNETIC SYMBOLS.

N	= north pole.	μ	= magnetic permeability.
S	= south pole.	k	= magnetic susceptibility.
m	= strength of pole.	H	= horizontal intensity of earth's magnetism.
H	= magnetic force (C. G. S.).	Z	= reluctance.
B	= magnetic inductance (C. G. S.).		
I	= intensity of magnetization.		

MEDICAL SIGNS AND ABBREVIATIONS.

R (Lat. Recipe), take; āā, of each; lb, pound; ℥, ounce; ℥, drachm; ℥, scruple; ℥, minim, or drop; O or o, pint; f ℥, fluid ounce; f ℥, fluid drachm; as, ℥ ss, half an ounce; ℥i, one ounce; ℥iss, one ounce and a half; ℥ij, two ounces; gr., grain; Q. S., as much as sufficient; Ft. Mist., let a mixture be made; Ft. Haust., let a draught be made; Ad., add to; Ad. lib., at pleasure; Aq., water; M., mix; Mac., macerate; Pulv., powder; Pil., pill; Solv., dissolve; St., let it stand; Sum., to be taken; D., dose; Dil., dilute; Filt., filter; Lot., a wash; Garg., a gargle; Hor., Decub., at bed time; Inject., injection; Gtt., drops; ss, one-half; Ess., essence.

SURVEYING SYMBOLS.

(U. S. Public Lands Surveys.)

The following contractions are authorized to be used in the preparation of field notes, transcripts, inspection reports and similar records, and no others should be introduced:

A.	for acres.	mag.	for magnetic
a. m.	" forenoon.	M. C.	" meander corner.
A. M. C.	" aux. meander corner.	mer.	" meridian.
asc.	" ascend.	mkd.	" marked.
astron.	" astronomical.	N.	" north.
bdy.	" boundary.	NE.	" northeast.
bdra.	" boundaries.	NW.	" northwest.
bet.	" between.	obs.	" observe.
B. O.	" bearing object.	obsn.	" observation.
B. T.	" bearing tree.	p. m.	" afternoon.
C. C.	" closing corner.	Pol.	" Polaris.
chs.	" chains.	Pr. Mer.	" principal meridian.
cor., cors.	" corner, corners.	Pt. of Tr.	" point of triangulation.
corr.	" correction.	$\frac{1}{4}$ sec.	" quarter section.
decl.	" declination.	R., Rs.	" range, ranges.
dep.	" departure.	red.	" reduce, reduction.
desc.	" descend.	S.	" south.
dia.	" diameter.	S. C.	" standard corner.
diff.	" difference.	SE.	" southeast.
dist.	" distance.	sec., secs.	" section, sections.
D. S.	" deputy surveyor.	S. M. C.	" special meander corner.
E.	" east.	sq.	" square.
elong.	" elongation.	St. Par.	" standard parallel.
frac.	" fractional.	SW.	" southwest.
ft.	" foot, feet.	T., or Tp.	" township.
G. M.	" guide meridian.	Ts. or Tps.	" townships.
h., hrs.	" hour, hours.	temp.	" temporary.
ins.	" inches.	U. C.	" upper culmination.
lat.	" latitude.	var.	" variation.
L. C.	" lower culmination.	W.	" west.
lks.	" links.	W. C.	" witness corner.
l. m. t.	" local mean time.	w. corr.	" watch correction.
long.	" longitude.	W. P.	" witness point.
m.	" minutes.	w. t.	" watch time.

For ordinary surveying abbreviations see general text on Surveying. Section 58.

1.—ELEMENTARY ARITHMETIC. NUMBERS.

Roman System.—This system is used in the arts, for dates, for numbering chapters in literature, and for distinctive numbering where the Arabic numerals will not suffice. It employs seven letters, corresponding with the Arabic numbers, as follows:

Roman....	I	V	X	L	C	D	M
Arabic....	1	5	10	50	100	500	1000

Higher basic denominations are sometimes represented by the letters C, D and M, *inverted*, but they are not in general use. The following table will be found useful in expressing any number by a combination of these letters.

1.—ROMAN NUMERALS.

Roman				Arabic Units.
Thousands.	Hundreds.	Tens.	Units.	
M	C	X	I	1
	CC	XX	II	2
	CCC	XXX	III	3
	CD	XL	IV	4
	D	L	V	5
	DC	LX	VI	6
	DCC	LXX	VII	7
	DCCC	LXXX	VIII	8
	DCCCC	XC	IX	9

To write any number in Roman system: Begin with the highest denomination of the number—tens, hundreds, thousands, etc.—and pick out the letter or letters in the Roman column, corresponding with that denomination and opposite the proper figure in the Arabic column; then proceed in the same manner with each figure of lower denomination. Thus, 3—III; 34—XXXIV—XXXIV; 648—DCXLVIII—DCXLVIII; 1799—M DCC XC IX—MDCCXCIX; 1900—MDCCC (preferred)—MCM.

Arabic System.

0	<i>Trillions.</i>
0	Hundred billions.
0	Ten billions.
0	<i>Billions.</i>
.	
9	Hundred millions.
8	Ten millions.
7	<i>Millions.</i>
.	
6	Hundred thousands.
5	Ten thousands.
4	<i>Thousands.</i>
.	
3	Hundreds.
2	Tens.
1	Units.
.	
1	Tenths.
2	Hundredths.
3	Thousandth.
.	
4	Ten thousandths.
5	Hundred thousandth.
6	Millionths.
0	
0	
0	
0	

This number is read thus: "Nine hundred eighty-seven million, six hundred fifty-four thousand, three hundred twenty-one . . . and one hundred twenty-three thousand, four hundred fifty-six, millionths." By moving the decimal point to the *right* or *left*, the number is respectively *multiplied* or *divided* by *ten*, times the number of *places* moved.

Primes, Multiples and Factors.—A prime number differs from a multiple in that it cannot be factored; that is, it is not *exactly* divisible by any other number, except 1. There is no known positive rule for detecting *all* prime numbers; tentative rules have been framed from time to time only to fail high up in the scale. But negative rules, universal in their application, may be stated as follows:

- (a.) No even number (2 excepted) is a prime, because divisible by 2.
- (b.) No number (3 excepted), the sum of whose digits is divisible by 3, is a prime, because itself divisible by 3. Example: 171 ($1+7+1=9$) is not a prime number, because 9 is divisible by 3.
- (c.) No number (5 excepted), ending in 5 or 0, is a prime, because divisible by 5. Examples: 15, 30, 125, are divisible by 5.
- (d.) No number composed of prime factors can have more than *one set* of prime factors. Example: $1001=7\times 11\times 13$; and 7, 11 and 13 is the *only set* of prime factors.

From the above we rightly conclude that all numbers, excepting 2 and 5, which end in 2, 4, 5, 6, 8 and 0, are multiple or composite; that a multiple may end in any figure; and that the ending of prime numbers is limited strictly to the digits 1, 3, 7 and 9. Furthermore, we may examine any number ending in 1, 3, 7 or 9 to see if the sum of the digits is a multiple of 3; if so, the number is composite and divisible by 3; but if not, it *may* be either prime or composite.

Table 2, following, contains a list of numbers up to 9600, which, by the preceding rules and analysis, cannot be detected as prime or composite. The numbers are composed of *hundreds* at the left of the *lines*, and *tens* and *units* at the top of the *columns*. At the intersection of the respective line and column of a number will be found the *smallest prime factor* (above unity) of that number. If the number is prime, the intersection will be represented by two dots.

The elimination, by Rule (b), of numbers ending in 1, 3, 7 and 9 which may be factored by 3, makes it convenient to separate the table into three parts by steps of 300, in order to condense it. The arrangement is as follows:

$3n+0$. This part (1) contains hundreds beginning with 0, as 000, 300, 600, 900, etc. Example: $2400=(3\times 8+0)$ hundreds.

$3n+1$. This part (2) contains hundreds beginning with 100, as 100, 400, 700, 1000, etc. Example: $5200=(3\times 17+1)$ hundreds.

$3n+2$. This part (3) contains hundreds beginning with 200, as 200, 500, 800, 1100, etc. Example: $3500=(3\times 11+2)$ hundreds.

Example.—What kind of a number is 27,489?

Solution.—The sum of its digits is 30, hence 3 is a factor. 3) 27489

From part 2 ($91=3n+1$) of table, the smallest factor of 9163 is 7. 7) 9163

From part 2 ($13=3n+1$) of table, the smallest factor of 1309 is 7. 7) 1309

From part 2 ($1=3n+1$) of table, the smallest factor of 187 is 11. 11) 187

From part 1 ($0=3n+0$) of table, 17 is found to be a prime. 17

Answer.—27489 is found to be a multiple or composite number whose prime factors are 3, 7, 7, 11 and 17; and from Rule (d) we learn that these are its *only* prime factors.

2.—PRIMES,* MULTIPLES AND FACTORS.

Part 1.—(3n+0) Hundreds.

(3n+0) Hundreds.	Tens and Units.

*The *smallest* prime factors of multiple numbers are given. Prime numbers are indicated by dots.

Example: To find the prime factors of 2413: The smallest prime factor, from above table, is 19; then, $2413 \div 19 = 127$. Now, from Part 2, on the following page, 127 is found to be a prime number. Hence, the prime factors of 2413 are 19 and 127.

*The *smallest* prime factors of multiple numbers are given. Prime numbers are indicated by dots.

Example: To find the prime factors of 3211: The smallest prime factor, from above table, is 13; then, $3211 \div 13 = 247$, the smallest prime factor of which is 13; then, $247 \div 13 = 19$, a prime number. Hence, the prime factors of 3211 are 13, 13 and 19.

Greatest Common Factor.—The *G. C. F.* of two or more numbers is the greatest factor common to all of them. It will be:

- 1st. A factor of all the numbers, therefore no greater than the least number;
 - 2nd. A factor of all the differences and successive differences except 0, therefore no greater than the least difference;
- And can be obtained (1) by differences, (2) by factoring, and (3) by division.

Example: Find the *G. C. F.* of 84, 126, 210 and 231.

1st Method.—By differences.

Ans.—The least difference, 21, is obviously the *G. C. F.* as it is the greatest common factor of the least number and of all the differences.

2nd Method.—By factoring.

(a).—Finding all the prime factors.

$$\begin{array}{r} 2)84 \\ 2)42 \\ 3)21 \\ \hline 7 \end{array} \quad \begin{array}{r} 2)126 \\ 3)63 \\ 3)21 \\ \hline 7 \end{array} \quad \begin{array}{r} 2)210 \\ 3)105 \\ 5)35 \\ \hline 7 \end{array} \quad \begin{array}{r} 3)231 \\ 7)77 \\ \hline 11 \end{array}$$

(b).—Finding all the common prime factors.

$$\begin{array}{r} 3)84 \\ 7)28 \\ \hline 4 \end{array} \quad \begin{array}{r} 126 \\ 42 \\ \hline 6 \end{array} \quad \begin{array}{r} 210 \\ 70 \\ \hline 10 \end{array} \quad \begin{array}{r} 231 \\ 77 \\ \hline 11 \end{array}$$

(c).—Finding the common factors.

$$\begin{array}{r} 21)84 \\ 4 \end{array} \quad \begin{array}{r} 126 \\ 6 \end{array} \quad \begin{array}{r} 210 \\ 10 \end{array} \quad \begin{array}{r} 231 \\ 11 \end{array}$$

3 and 7 are common

3 and 7 are common to all—21.

to all—21.

By inspection—21.

3rd Method.—By division (this is simply another form of differences).

$$\begin{array}{r} 84)126(1 \\ \underline{84} \\ 42)84(2 \\ \underline{84} \end{array}$$

$$\begin{array}{r} 210 \\ 42)210(5 \\ \underline{210} \end{array}$$

$$\begin{array}{r} 231 \\ 42)231(5 \\ \underline{210} \\ 21)42(2 \\ \underline{42} \end{array}$$

Rule.—Start with any two of the numbers. Divide the greater by the less and if there is a remainder use this remainder as a divisor of the previous divisor, and continue until there is no remainder. The last divisor will be the greatest common divisor or *G. C. F.* of the two numbers. Use this *G. C. F.* so obtained with the next number for a new *G. C. F.*, and so on until all the numbers are exhausted. The last divisor without a remainder will be the *G. C. F.* of all the numbers.

Least Common Multiple.—The *L. C. M.* of two or more numbers is the least number that can be divided exactly by each of them.

Rule for finding the *L. C. M.*—Divide the given numbers by the greatest (or any) factor common to most of them, and if divisible, set down the quotients in the line below; but if not divisible, bring down the numbers themselves. Divide the new line of numbers in a similar manner, and also each successive line, until no two numbers have a common factor except 1. The *L. C. M.* will be the product of all the factors and the last line of numbers. During the process, if any number is a factor of any other number in the same line it can be cancelled.

Example 1.

Find the *L. C. M.* of 7, 24, 168 and 264.

$$\begin{array}{r} 4 \mid 7 \quad 24 \quad 168 \quad 264 \\ 6 \mid 7 \quad 6 \quad 42 \quad 66 \\ 7 \mid 7 \quad \quad 7 \quad 11 \\ \hline 11 \end{array}$$

Ans.— $4 \times 6 \times 7 \times 11 = 1848$.

Example 2.

Find the *L. C. M.* of 13, 28, 52 and 84.

$$\begin{array}{r} 4 \mid 13 \quad 28 \quad 52 \quad 84 \\ 13 \mid \quad 7 \quad 13 \quad 21 \end{array}$$

NOTE.—13 is a factor of 13, and 7 of 21

Ans.— $4 \times 13 \times 21 = 1092$.

Note that the first line in each example above could have been divided by 2, and then again by 2, instead of by 4; and that the second line in Example 1 could have been divided by 2 and then by 3, instead of by 6,

The *L. C. M.* of two numbers is obviously a special case of the above in which the product of the factors is the *G. C. F.*, and the last line of numbers are quotients obtained by dividing the respective numbers by their *G. C. F.* Thus, in Example 3, the *L. C. M.* of 126 and 462 is their *G. C. F.* (= 42) multiplied by the product of their respective

Example 3.
Find the *L. C. M.* of 126 and 462.

6	126	462
7	21	77
	3	11

Ans.— $(6 \times 7) \times 3 \times 11 = 1386$.

quotients, $\frac{126}{42} = 3$, and $\frac{462}{42} = 11$.

FRACTIONS.

Kinds of Fractions.

Common Fractions.	Simple	Proper.— $\frac{1}{2}$, $\frac{1}{3}$.
		Improper.— $\frac{4}{3}$, $\frac{5}{2}$.
	Mixed.	$2\frac{1}{2}$, $5\frac{1}{3}$.
	Compound.	$-\frac{1}{2}$ of 4, $\frac{1}{3}$ of $3\frac{1}{2}$.
Decimals.	Complex.	$-\frac{1}{3}$, $\frac{1}{4}$, $\frac{2}{3}$, $\frac{5}{4}$.
	Pure.	$-.25$, $.625$.
	Mixed.	-1.25 , 4.875

Equivalent values.

$\frac{3}{5} = \frac{3n}{5n} = \frac{3 \times 2}{5 \times 2} = \frac{6}{10} = .6$.	Both terms of a fraction may be multiplied or divided by the same number without affecting its value.
$\frac{3}{2} = \frac{3+2}{2} = \frac{5}{2} = 2\frac{1}{2} = 1\frac{1}{2}$.	
$2\frac{1}{2} = \frac{5}{2} = \frac{5}{2} = 2\frac{1}{2}$.	
$\frac{1}{2}$ of $3\frac{1}{2} = \frac{1}{2} \times 3\frac{1}{2} = \frac{2}{3} \times \frac{6+1}{2} = \frac{2}{3} \times \frac{7}{2} = \frac{7}{3} = 2\frac{1}{3}$.	
$2\frac{1}{2} = \frac{5}{2} + 3\frac{1}{2} = \frac{5}{2} + \frac{7}{2} = \frac{5}{2} \times \frac{2}{7} = \frac{5}{7}$.	
$.25 = \frac{.25}{1} = \frac{2.5}{10} = \frac{25}{100} = \frac{100}{400} = \frac{10}{40} = \frac{1}{4}$.	
$4.875 = 4\frac{875}{1000} = 4\frac{888}{888} = 4\frac{1}{8}$.	

To reduce to lowest terms.—Divide both terms of the fraction by their greatest common factor; or factor them as in finding their *G. C. F.* Thus,

$$\frac{12}{30} = \frac{12 \div 6}{30 \div 6} = \frac{2}{5}, \text{ or } \frac{12}{30} = \frac{6}{15} = \frac{2}{5}.$$

To reduce to a common denominator.—Reduce the fractions (generally) to their lowest terms and find the least common multiple of their denominators for a common denominator. Then expand both terms of each fraction proportionately so that their denominators will be equal to the common denominator. Thus, $\frac{1}{2}$, $\frac{1}{3}$, $\frac{1}{4}$ and $\frac{1}{5}$ = $\frac{1}{2}$, $\frac{1}{3}$, $\frac{1}{4}$ and $\frac{1}{5}$. The *L. C. M.*

of their denominators = 72. Hence, $\frac{1}{2} = \frac{1 \times 36}{72} = \frac{36}{72}$, $\frac{1}{3} = \frac{8 \times 7}{72} = \frac{56}{72}$, $\frac{1}{4} = \frac{9 \times 5}{72} = \frac{45}{72}$ and $\frac{1}{5} = \frac{24 \times 1}{72} = \frac{24}{72}$.

To Change—

(a). An improper fraction to a mixed number.

$$\frac{177}{32} = ? \quad \text{Ans. } 5\frac{17}{32}.$$

Rule.—Divide the numerator by the denominator. The quotient is the whole number, and the remainder the new numerator.

Process:

$$\begin{array}{r} 32 \overline{) 177} \\ \underline{160} \\ 17 \end{array}$$

- (b.) *A mixed number to an improper fraction.* $14\frac{5}{9} = ?$ Ans. $\frac{131}{9}$.
 Rule.—Multiply the integral part by the denominator, add the numerator, and place the sum over the denominator.
 Process.

$$\begin{array}{r} 14 \\ 9 \\ \hline 126 + 5 = 131. \end{array}$$
- (c.) *A whole number to an improper fraction.* $6 = \frac{?}{15}$ Ans. $\frac{90}{15}$.
 Rule.—Multiply the whole number by the given denominator for the required numerator.
 Process.
 $6 \times 15 = 90.$
- (d.) *A compound to a simple fraction.* $\frac{2}{3}$ of $\frac{5}{8} = ?$ Ans. $\frac{5}{12}$.
 Rule.—Proceed as in multiplication. ("Of" means "times.") Place the product of the numerators over the product of the denominators, and reduce to lowest terms. Cancel, generally, before multiplying.
 Process.

$$\frac{2}{3} \times \frac{5}{8} = \frac{5}{12}$$
- (e.) *A complex to a simple fraction.* $2\frac{1}{3} = ?$ Ans. $\frac{7}{3}$.
 Rule.—Reduce the numerator and denominator each to simple fractions; then multiply the numerator by the denominator inverted.
 Process.

$$2\frac{1}{3} = \frac{7}{3} = \frac{7}{3} \times \frac{2}{2} = \frac{14}{6} = \frac{7}{3}$$

Cancellation.—In practical operations where the multiplication of various kinds of numbers, including fractions, is expressed, the process may often be shortened by cancellation. Thus, let it be required to find the product of $1\frac{1}{2}$, $\frac{2}{3}$, and $\frac{1}{4}$. Clearly, we may place the product of the numerators over the product of the denominators for a simple fraction expressing the result, or we may go to the other extreme and cancel as long as factors will cancel each other. There is, however, a medium point where cancellation may sometimes cease for simplicity of operation.

Thus,
$$\frac{315 \times 4 \times 5}{400 \times 25 \times 9} = \frac{700}{10000} \quad (\text{The denominator is a power of 10.})$$

Addition of Fractions.—Reduce to the smallest common denominator and add the new numerators. Thus, $\frac{1}{2} + \frac{1}{3} = \frac{3}{6} + \frac{2}{6} = \frac{5}{6}$; $1\frac{1}{2} + \frac{2}{3} = \frac{3}{2} + \frac{4}{6} = \frac{9}{6} + \frac{4}{6} = \frac{13}{6} = 2\frac{1}{6}$; $1\frac{1}{2} + 15\frac{1}{3} = \frac{3}{2} + \frac{10}{1} = \frac{3}{2} + \frac{20}{2} = \frac{23}{2} = 11\frac{1}{2}$; or, $1\frac{1}{2} + 15\frac{1}{3} = 16 + \frac{1}{2} + \frac{1}{3} = 16 + \frac{3}{6} + \frac{2}{6} = 16 + \frac{5}{6} = 16\frac{5}{6}$.

Subtraction of Fractions.—Reduce to the smallest common denominator and find the difference of the new numerators. Thus, $\frac{1}{2} - \frac{1}{3} = \frac{3}{6} - \frac{2}{6} = \frac{1}{6}$; $8\frac{1}{2} - 3\frac{1}{3} = 8\frac{3}{6} - 3\frac{2}{6} = 7\frac{1}{6}$; $8\frac{1}{2} - 3\frac{1}{3} = 7\frac{1}{6}$.

Multiplication of Fractions.—If necessary, change to simple fractions; cancel where advisable, and place the product of the numerators over the product of the denominators; reduce to required form. Thus, $\frac{1}{2} \times \frac{2}{3} = \frac{1}{3}$;

$$2\frac{1}{2} \times \frac{2}{3} \times 1\frac{1}{2} = \frac{9}{4} \times \frac{2}{3} \times \frac{35}{18} = \frac{5}{4} = 1\frac{1}{4}.$$

Division of Fractions.—If necessary, change to simple fractions; invert the divisor and multiply. Thus, $32\frac{1}{2} \div 6\frac{1}{2} = \frac{261}{8} \div \frac{27}{4} = \frac{261}{8} \times \frac{4}{27} = \frac{29}{6} = 4\frac{5}{6}$.

To reduce a fraction to a reciprocal.—Divide the denominator by the numerator, writing the quotient in decimal form. Thus, the reciprocal of $\frac{1}{3.2} = \frac{1}{3.2} = \frac{10}{32} = 3.2$. Hence, instead of dividing a number by $\frac{1}{3.2}$ we may multiply it by 3.2.

To reduce a common fraction to a decimal.—Divide the numerator by the denominator, writing the quotient in decimal form. Thus,

$$\frac{1}{3} = \frac{1000}{3000} = .333\ldots$$

3.—FRACTIONS (7THS) REDUCED TO DECIMALS.

NOTE.—These decimals are all *repeating* decimals, that is, they contain figures or groups of figures that may be repeated or annexed indefinitely. Thus, $\frac{1}{7} = .142857^{*}142857^{*}142857^{*}1 \dots = .142857^{*}1$, the inverted caret (^) signifying that the figure following is the first of the repeating group. Examples: $\frac{1}{7} = .1^{*}1 = .1111^{*}1 = .1111111^{*}1 \dots$; $\frac{2}{7} = .2^{*}857142 = .2857142^{*}857142^{*}8$, etc.

DECIMALS.

Addition of Decimals.—Have the decimal points "in column" before adding.

Example:
$$\begin{array}{r} 2.0625 \\ 315.25 \\ .0375 \\ \hline 317.3500 \end{array}$$

Subtraction of Decimals.—Have the decimal points "in column" before subtracting.

Example:
$$\begin{array}{r} 15.125 \\ 3.71825 \\ \hline 11.40675 \end{array}$$

Multiplication of Decimals.—Multiply as with whole numbers; the product to have as many decimal places as the factors combined. Thus, $2.3 \times .05 \times 7.22 = .83030 = .8303$.

Example:
$$\begin{array}{r} 6.75 \\ 2.4 \\ \hline 2700 \\ 1350 \\ \hline 16.200 \end{array}$$

Division of Decimals.—Multiply or divide the divisor and dividend by some power of 10 that will make the divisor a whole number of significant figures, marking the new decimal point in the dividend by a caret (^). The quotient will then contain as many decimal places as the new dividend. Example: Divide 17.34 by 600?

Example:
$$\begin{array}{r} \text{Divide } 3573.2 \text{ by } 2.375. \\ \text{Ans. } 1504.505 + \\ 1504.505 + \\ \hline 2.375 \overline{) 3573.200}^{\wedge} \\ 2375 \\ \hline 11982 \\ 11875 \\ \hline 10700 \\ 9500 \\ \hline 12000 \\ 11875 \\ \hline 12500 \\ 11875 \end{array}$$

$$\begin{array}{r} 600 \overline{) 17.34} \\ .0289 \text{ Ans.} \end{array}$$

Example: Divide 17.34 by .006?

$$\begin{array}{r} .006 \overline{) 17.340} \\ 2890 \text{ Ans.} \end{array}$$

To reduce a decimal to a common fraction.

a.) **Exact decimals.**—For the numerator of the fraction, use the significant figures of the decimal, the denominator being 1 with as many ciphers annexed as there are decimal places in the decimal; reduce to lowest terms.

Thus, $.75 = \frac{75}{100} = \frac{3}{4}$; $.0072 = \frac{72}{10000} = \frac{9}{1250}$

(b.) *Repeating decimals.*—Treat the *non-repeating* and the first *repeating* groups as a whole number; subtract from this the non-repeating group treated as a whole number; the difference will be the numerator of the fraction. The denominator will be composed of as many 9's as there are repeating figures in a group, followed by as many 0's as there are non-repeating figures. Reduce to lowest terms.

Example: Reduce $.3\overline{7}$ to a fraction. Example: Reduce $.46\overline{78}$ to a fraction.

$$\begin{array}{r} \text{num. } \frac{3}{9} = \frac{1}{3} \text{ Ans.} \\ \text{denom. } 9 \end{array}$$

$$\begin{array}{r} \text{num. } \frac{463}{990} \text{ Ans.} \\ \text{demon. } 990 \end{array}$$

ADDITION.

The following examples serve to illustrate approved methods:

Add:	Same by columns:	Add:	Reduced to eighths:	Reduced to decimals:

6.74	6.74	3½ × 2½ = 15 × 7 / 4 × 3 = 8½
5056	50	3.75 × 2½ = 7.5 + 1.25 = 8.75
8848	885	.2 × .3 = .06
7584	7584	.111
Ans. 85.1936	Ans. 85.19	.3
		.0333

A few short methods of multiplication will be found useful:

(1.) *By reducing the multiplier* to an improper fraction with a simple numerator and denominator.* Where the numerator becomes 1, 10, 100, 1000, etc., it is known as the reciprocal method. In the following, let n represent the number to be multiplied:

$n \times 1\frac{1}{2} = \frac{10n}{8}$	$n \times 8\frac{1}{2} = \frac{100n}{12}$	$n \times 66\frac{2}{3} = \frac{200n}{3}$
$\times 1\frac{1}{3} = \frac{10n}{6}$	$\times 12\frac{1}{2} = \frac{100n}{8}$	$\times 83\frac{1}{3} = \frac{1000n}{12}$
$\times 2\frac{1}{2} = \frac{10n}{4}$	$\times 16\frac{2}{3} = \frac{100n}{6}$	$\times 166\frac{2}{3} = \frac{1000n}{6}$
$\times 3\frac{1}{2} = \frac{10n}{3}$	$\times 25 = \frac{100n}{4}$	$\times 333\frac{1}{3} = \frac{1000n}{3}$
$\times 6\frac{1}{2} = \frac{100n}{4 \times 4}$	$\times 33\frac{1}{2} = \frac{100n}{3}$	
$\times 6\frac{1}{2} = \frac{20n}{3}$	$\times 50 = \frac{100n}{2}$	

See also Reciprocals, page 30.

* If the multiplier is $1\frac{1}{2}$, add $\frac{1}{2}$.
 " " " $13\frac{1}{2}$, " $\frac{1}{2}$ and multiply by 10.
 " " " $133\frac{1}{2}$, " $\frac{1}{2}$ and multiply by 100.

(2). When the sum of the unit figures equals 10; and balance of numbers are identical:

11	12	15	24	48	96	124	243
19	18	15	26	42	94	126	247
209	216	225	624	2016	9024	15624	60021

Rule.—Multiply the unit figures together, occupying two places (see first example above); and prefix the product of the *balance* of either number by (itself + 1).

(a.) Special Case.—When the last figure is 5 the last two figures of the product will be 25; thus, $25^2 = 625$, $95^2 = 9025$, $145^2 = 21025$, $245^2 = 60025$; all performed mentally.

(b.) Special Case.—When the last figure in each number is a decimal, and their sum is unity, the whole numbers being identical; thus,

$$1.1 \times 1.9 = 2.09, \quad 2.4 \times 2.6 = 6.24, \quad 24.3 \times 24.7 = 600.21$$

(c.) Special Case.—When the whole numbers are identical and the numbers contain fractions (instead of decimals, as above) whose sum is unity; thus,

$$1\frac{1}{2} \times 1\frac{1}{2} = 2\frac{1}{4}, \quad 1\frac{1}{3} \times 1\frac{1}{3} = 2\frac{1}{9}, \quad 12\frac{1}{2} \times 12\frac{1}{2} = 156\frac{1}{4}.$$

(3). The product of any two numbers each ending with the fraction $\frac{1}{2}$, or with the decimal .5:

$$9\frac{1}{2} \times 3\frac{1}{2} = 9 \times 3 + \frac{9+3}{2} + \frac{1}{4} = 33\frac{1}{4}.$$

$$7.5 \times 11.5 = 77 + 9 + .25 = 86.25.$$

Rule.—*The product of the whole numbers + half their sum + $\frac{1}{4}$.

(a.) Special Case.—When the numbers are whole numbers ending with 5:

$$95 \times 35 = 100(27 + 6 + .25) = 3325.$$

$$75 \times 115 = 100(77 + 9 + .25) = 8625.$$

$$185 \times 305 = 100(540 + 24 + .25) = 56425.$$

Rule.—Apply the general rule above, considering each number divided by 10, and multiply the result by 100.

(4.) †The product of any two numbers is equal to the square of their mean, minus the square of half their difference:

$$24 \times 26 = 25^2 - 1 = 624. \quad 136 \times 144 = 140^2 - 16 = 19584.$$

$$87 \times 93 = 90^2 - 9 = 8091. \quad 244 \times 256 = 250^2 - 36 = 62464.$$

(5.) †The converse of (4), of course, holds true and may be applied readily in finding the squares of numbers—considering them as means:

$$39^2 = 38 \times 40 + 1 = 1521. \quad 68^2 = 66 \times 70 + 2^2 = 4624.$$

Note.—Use for a base, any multiple of 10 nearest the number to be squared.

(6.) †The square of any number is equal to the square of (itself ± 1), called the base, $\mp$ the sum of the base and the number:

$$39^2 = 40^2 - 79 = 1521. \quad 71^2 = 70^2 + 141 = 5041.$$

(7.) Miscellaneous Methods.†

a.) To multiply any number n by 11.

Note.—Imagine the number, and its product by 10, arranged thus:

$$\begin{array}{r} 879687 \\ 879687 \text{ for addition} \end{array}$$

$$n = 879,687$$

$$\text{Ans. } 9,676,557$$

(b.) To multiply a number n by any number from 12 to 19, inclusive:

Example: Multiply 7364 by 17.

Note.—When the unit figure of the multiplier is 1, the same principle of course holds true; as, for instance, 7364×71

$$n = 7364$$

$$n \times 7 = 51548$$

$$\text{Ans. } 125,188$$

$$7364$$

$$+ 51548$$

$$= 522,844$$

(c.) To multiply a number n by any number from 92 to 99, inclusive:

Example: Multiply 7364 by 98.

$$100n = 736400$$

$$- 2n = 14728$$

$$\text{Ans. } 721,672$$

d.) When the multiplier contains simple factors.

it may be quicker to use the factors:

Example: Multiply 987 by 64.

$$987$$

$$n \times 8 = 7896$$

$$n \times 8 \times 8 = 63168. \text{ Ans.}$$

* From Algebra: $(a + c)(b + c) = ab + c(a + b) + c^2$.

† From Algebra: $(x + y)(x - y) = x^2 - y^2$.

‡ From Algebra: $(x \pm 1)^2 = x^2 \pm 2x + 1$.

§ These illustrations may be expanded almost indefinitely.

DIVISION.

Accurate:

$$\begin{array}{r}

 28 \ 65
 \end{array}$$

There are short special methods of division, but they are usually not broad enough in their application to record for general use.

(a.) Factor the divisor:

Example: Divide 972 by 16.

$$\begin{array}{r}
 4 \overline{) 972} \\
 \underline{4 \overline{) 243}} \\
 60\frac{1}{2} \text{ Ans.} \\
 43.2 \\
 \underline{.4} \\
 17.28 \text{ Ans.}
 \end{array}$$

(b.) Multiply by the reciprocal:

Example: Divide 43.2 by 2.5

(c.) To divide by a fraction, invert it and multiply, but reducing it to a simple decimal or reciprocal if possible:

$$\frac{1}{2} \div \frac{1}{4} = \frac{1}{2} \times \frac{4}{1} = 2. \quad 56 \div \frac{1}{2} = 56 \times 2 = 112.$$

(d.) Cancellation: $\frac{3 \times 9 \times 16}{2 \times 12 \times 18} = \frac{8}{3} = 2\frac{2}{3} \text{ Ans.}$

2.—POWERS, ROOTS AND RECIPROCALs.

The processes of multiplication and division, and of finding the powers, roots and reciprocals of numbers may be performed by arithmetic (and algebra); by the use of tables; by logarithms;* or by the logarithmic slide rule.†

A. ENGINEERS' TABLES.

Under the present heading will be found Engineers' Tables of powers, roots and reciprocals of numbers arranged in form similar to logarithmic tables, so that the above properties of any number can be obtained by manipulating the decimal point, and by the use of the proportional parts (P. P.) columns, as in finding the logarithms of numbers. These tables may also be used inversely in finding the squares, cubes, and inverse reciprocals, corresponding respectively to the square, roots, cube roots and reciprocals—the process being similar to finding the numbers corresponding to given logarithms. For a more academic arrangement see Arithmetical Tables 9, 10, and 11, following.

Square Root.—Tables 1 and 2, following, comprise a 4-page table of the square roots of numbers. The first two pages (Table 1) are for numbers with an odd number of figures to the left of the decimal point; or, if it is a pure decimal the first significant figure must be an even number of places to the right of the decimal point. The last two pages (Table 2) are for numbers just the reverse—even to the left and odd to the right. The range of the tables may be extended by remembering that "changing two decimal points in the square—one decimal point in the root—in the same direction." The tables are logarithmic in form, containing P. P. columns for extension or interpolation.

Example.—Required the square root of 907.6.

Solution.—Three figures at the left of the decimal point calls for the "odd" table (Table 1), from which the sq. rt. of 907 = 30.116, and the proportional part of the difference, 17, between it and the next higher number, 908, is found to be 10 (10.2) which, added to 30.116 = 30.126. Ans.

The following methods are given for extracting the square root when tables are not accessible, or when great accuracy is desired, for large numbers:

By Algebra.		By Arithmetic.	
Square root of $a^2 + 2ax + x^2$?		Square root of 576 ?	
$a^2 + 2ax + x^2$ ($a + x$. Ans.	Assume $x = 4$	$2a = 40$	576 (20 + 4 = 24. Ans.
a^2		400	
$2a + x$) $2ax + x^2$		$2a + x = 44$) 176	$a = 20,$
$2ax + x^2$		176	$x = 4.$

Example.—Extract the square root of 46,354.87 ?

Remarks.—Beginning with the unit figure, point off two places each way, forming groups of two figures to bring down each time. Proceed as indicated.

		Process:	
		46354.87 (215.301 + . Ans.	
		4	
Assume $a_1 = 20$ }	$\therefore 2a_1 + x_1 = 41$	63	$a_0 = 2,$
$x_1 = 1$ }		41	$a_1 = 20, x_1 = 1$
Assume $a_2 = 210$ }	$\therefore 2a_2 + x_2 = 425$	2254	$a_2 = 210, x_2 = 5$
$x_2 = 5$ }		2125	
Or,	$215 \times 2 = 430;$	4303	12987
			12909
	$2153 \times 2 = 4306;$	430601	780000

* See table of logarithms, page 108.

† For description and use of the slide rule, see page 126.

Example.—Extract the square root of 4,635.4?

Note that the position of the decimal point affects the pointing off and, consequently, the entire character of the result.

Process:

$$\begin{array}{r}
 \dot{4}6\dot{3}5.\dot{4}0 \text{ (68.08+ Ans.} \\
 \quad 36 \\
 128 \overline{)1035} \\
 \quad 1024 \\
 13608 \overline{)114000} \\
 \quad 108864
 \end{array}$$

Odd.

Even.

1.—SQUARE ROOTS (AND SQUARES*) OF NUMBERS—

NOTE.—The square must contain an odd number of figures to the left of the decimal point. If the square is a *pure decimal*—less than unity—the first significant figure must be an *even* number of places to the right of the decimal point. See page 14 for explanation of table.

*Square Roots are obtained directly as in the logarithmic tables, using the Proportional Parts tables for interpolation.

Squares may be obtained by inverse interpolation.

Example.—Square root of $374.9 = 19.339$

+ 23

= 19.362 Ans.

Odd.

Even.

Odd.

2.—SQUARE ROOTS (AND SQUARES*) OF NUMBERS—

NOTE.—The square must contain an even number of figures to the left of the decimal point. If the square is a pure decimal—less than unity—the first significant figure must be an odd number of places to the right of the decimal point. See page 14 for explanation of table.

Changing 2 decimal points in the square = 1 decimal point in the root.

*Square Roots are obtained directly as in the logarithmic tables, using the Proportional Parts column for interpolation.

Squares may be obtained by inverse interpolation.

Even.

Odd.

—FROM 10 TO 100; 1,000 TO 10,000; ETC.

Changing 2 decimal points in the square — 1 decimal point in the root.

Ex.—Cube root of 887.2?

Solution—9.6082 for 887
7 for .2

Ans. 9.6089 for 887.2

The dash (-) is to be supplied by figs. 0 to 9 at the head of the respective column.

Changing 2 decimal places in $N = 5$ decimal places in $\sqrt{N^5}$, in the same direction.

Note that $\sqrt{N^5} = N^{\frac{5}{2}} = N^2 \times \sqrt{N} = N^2 \times N^{\frac{1}{2}} = N^2 \times \sqrt{N}$. Hence, the above values may be obtained by multiplying together the square and the square root of the respective numbers.

*Powers (N^5) are obtained directly as in the logarithmic tables; roots (N), by inverse interpolation.

Note that $N^5 = N^{2+3} = N^2 \times N^3$. Hence, the above values may be obtained by multiplying together the square and the cube of the respective numbers.

—AND ANY WHOLE NUMBER; OR DECIMAL.

*Reciprocals to four decimal places on this page.

Ex.—Find reciprocal of 2.743?

Solution—0.3650

—4

Reciprocal of 27.43 = 0.03646; of 0.2743 = 3.646; etc.

0.3646 Ans.

5 to 10.

—WHOLE AND DECIMAL.

Changing the decimal point N places in the number N places in the opposite direction in the reciprocal.

†Reciprocals to five decimal places on this page.

Ex.—Find reciprocal of 1.2368 by the inverse method.

Solution—8.08 for 0.12376

.005 —8

8.085 for 0.12368

∴ Ans. = 0.8085 for 1.2368

Reciprocals.—The reciprocal of a number is 1 divided by that number. Thus, the reciprocal of 2.77 = .361, and likewise the reciprocal of .361 is 2.77; or $2.77 = 1/.361$ and $.361 = 1/2.77$. Hence, to divide any quantity by a number, as 2.77, is equivalent to multiplying it by its reciprocal, $1/2.77$ or .361.

As multiplication is usually performed more readily than division, it is convenient to multiply by the reciprocal of a number rather than to divide by the number itself.

Table 8* comprises the reciprocals of numbers from 1 to 10, advancing by decimals as in logarithmic tables, so as to include a wide range of numbers. Note that changing the decimal point n places in the number equals a change of n places in the *opposite direction* in the reciprocal; also that the differences between any reciprocal and the following one is a *minus difference*, hence the proportional part must be *subtracted*.

Example.—What is the reciprocal of 79.15?

Solution.—From the table, the reciprocal of 7.91 = .12642; the proportional part for 5 (under the difference, —16) is —8. Hence, the reciprocal of 7.915 is .12634, and of 79.15 is 0.012634. Ans.

B. ARITHMETICAL OR COMMON TABLES.

The preceding tables are arranged in decimal form, and are called Engineers' Tables; while the arithmetical tables are in the form most commonly used, and are arranged as follows:—

Table 9—Squares, cubes, square roots, cube roots, of numbers, 1 to 1000, page 31:

Nos. 0—130, page 31.	Nos. 910—1040, page 38.

3.—PRACTICAL ARITHMETIC.

PROPORTION.

As Algebra is the *shorthand* of Mathematics so is Proportion the *key* to many of its operations. Indeed, all mathematical problems may be expressed in proportion.

Ratio is an expression of the relative magnitude of two quantities in the form of a fraction, either term of which may be considered the unit of measure. Thus, the ratio of the yard to the foot may be expressed as $\frac{Y}{F}$ or $Y : F$, in which case, however, Y and F must be considered in the same unit of measure, yard or foot. Every ratio *implies* proportion, as $\frac{Y}{F} = \frac{x}{1} = \frac{3}{1}$; $F : 1 = Y : x$; etc.

Proportion is the equality of two or more ratios, and it may be represented graphically by similar triangles, as in Fig. 1, from which may be obtained a variety of expressions, as follows:

By proportional lengths (also illustrating *continued proportion*):

Fig. 1.

$$\left\{ \frac{P}{B} = \frac{p}{b} = \frac{p_1}{b_1} = \frac{p+p_1}{b+b_1} = \frac{P+p}{B+b} = \frac{P+p_1}{B+b_1} = \frac{P+p+p_1}{B+b+b_1}, \text{ etc. (or inverted).} \right.$$

$$\left\{ \frac{12}{16} = \frac{9}{12} = \frac{3}{4} = \frac{9+3}{12+4} = \frac{12+9}{16+12} = \frac{12+3}{16+4} = \frac{12+9+3}{16+12+4}, \text{ etc. (or inverted).} \right.$$

$$\left\{ \frac{P}{B} = \frac{p-p_1}{b-b_1} = \frac{P-p}{B-b} = \frac{P-p_1}{B-b_1} = \frac{P-p-p_1}{B-b-b_1}, \text{ etc. (or inverted).} \right.$$

$$\left\{ \frac{12}{16} = \frac{9-3}{12-4} = \frac{12-9}{16-12} = \frac{12-3}{16-4} = \frac{12-9-3}{16-12-4}, \text{ etc. (or inverted).} \right.$$

$$\frac{P}{H} = \frac{p}{h} = \frac{p_1}{h_1}; \text{ and } \frac{B}{H} = \frac{b}{h} = \frac{b_1}{h_1} \text{ may likewise be extended (or inverted).}$$

By proportional squares (also illustrating *compound proportion*):

$$H^2 : h^2 : h_1^2 :: P^2 + B^2 : p^2 + b^2 : p_1^2 + b_1^2; \text{ or } \frac{H^2}{h^2} : \frac{h_1^2}{h^2} = \frac{P^2 + B^2}{p^2 + b^2} : \frac{p_1^2 + b_1^2}{p^2 + b^2}.$$

$$20^2 : 15^2 : 9^2 :: 12^2 + 16^2 : 9^2 + 12^2 : 3^2 + 4^2; \text{ or } \frac{20^2}{15^2} : \frac{9^2}{15^2} = \frac{12^2 + 16^2}{9^2 + 12^2} : \frac{3^2 + 4^2}{9^2 + 12^2}.$$

In the above some of the ratios are compound ratios, hence the term *compound proportion*.

Simple Proportion or single rule of three deals with two simple, equal ratios. Thus,

Extreme : mean = mean : extreme
 $P : B :: p : b$
 reads, "As P is to B so is p to b ." The first and last terms are called the *extremes*, and the middle terms the *means*. In any simple problem there will

* From $\frac{P}{B} = \frac{p}{b}$ we have $Pb = pB$, whence $\frac{P}{p} = \frac{B}{b}$, or $\frac{b}{p} = \frac{B}{P}$ or $\frac{b}{B} = \frac{p}{P}$, etc.

be one unknown term which can be solved by applying the rule: *The product of the means is equal to the product of the extremes.*

Fig. 2.

Problem.—If a train travels 280 miles in 7 hours, how far will it travel in 5 hours?

Solution.—From similar triangles there is obtained,

$7 : 5 = 280 : x$

from which, applying the above rule,

$$7x = 5 \times 280$$

$$\text{or } x = \frac{5 \times 280}{7} = 200 \text{ miles. Ans.}$$

Mean Proportional.—In any proportion where the two means are equal to each other, they are each said to be a mean proportional between the extremes. In the accompanying geometrical figure, b , an ordinate to the circumference, is a mean proportional between a and c , composing the diameter, as, from similar triangles there will obtain the proportion

Fig. 3.

$$a : b = b : c$$

$$\text{or } 4 : 6 = 6 : 9$$

whence $6 = \sqrt{4 \times 9}$; or, the *mean* = $\sqrt{\text{product of extremes}}$.

Inverse Proportion.—This term is used in such problems as those where the rate of speed or velocity are compared, when the total time, distance, amount of work, etc., are given; as, the rate of work is *inversely proportional* to the time occupied in doing it; or, the speed of a train is *inversely proportional* to the time used in traveling a certain distance.

Compound Proportion or double rule of three.—Compound proportion is merely simple proportion in which two or more of the ratios are compounded.

Problem.—If a man saws 18 cords of wood in 12 days of 9 hours each, how many cords of wood can he saw in 15 days of 8 hours each?

$$\text{Solution.}—\frac{18}{12 \times 9} = \frac{x}{15 \times 8}; \text{ whence } x = \frac{18 \times 15 \times 8}{12 \times 9} = 20 \text{ days. Ans.}$$

A little thought coupled with a graphical conception of the problem will always point to a correct grouping of the terms.

PERMUTATION AND COMBINATION.

Permutation.—The number of different ways in which any number, N , of objects may be arranged in line or counted, is equal to the product of all the numbers from 1 to N . Thus, 3 objects as a, b and c may be arranged $1 \times 2 \times 3 = 6$ different ways in line— $abc, acb, bac, bca, cab, cba$; 7 objects may be arranged $1 \times 2 \times 3 \times 4 \times 5 \times 6 \times 7 = 5040$ different ways, and so on.

Combination.—The number of different groups each composed of n objects (no two groups to be composed of the same objects) which can be formed separately from any number N , of objects, is equal to the product of all the numbers from $(N - n + 1)$ to N , divided by the product of all the numbers from 1 to n . (It must be remembered that the objects in each group are *not* permuted.) Thus, 6 objects as a, b, c, d, e and f may be

arranged in groups of 2, $\frac{5 \times 6}{1 \times 2} = 15$ different ways; thus,

$ab,$	$ac,$	$ad,$	$ae,$	$af,$
	$bc,$	$bd,$	$be,$	$bf,$
		$cd,$	$ce,$	$cf,$
			$de,$	$df,$
				$ef,$

Similarly, 8 objects may be arranged in groups of 4,

$$\frac{5 \times 6 \times 7 \times 8}{1 \times 2 \times 3 \times 4} = 70 \text{ different ways.}$$

ALLIGATION.

The average cost of a mixture containing various quantities of ingredients at different unit prices may be obtained by dividing the total cost of the mixture by the total quantity. Let it be required to find the average cost of a mixture as follows:

10 bbls. cement @ \$2.00	= \$ 20.
20 " " 2.25	= 45.
30 " " 2.50	= 75.

∴ 60

= \$140.

Average price per bbl. = $\frac{140}{60} = \$2.33\frac{1}{3}$. Ans.

This problem is analogous to finding the position of the center of gravity and resultant of a system of concentrated loads, in Mechanics.

Fig. 4.

PROGRESSION.

Arithmetical Progression.—An arithmetical series or progression consists of a series of terms which uniformly increase or decrease by a common constant difference, d . Thus,

Ascending:

$(d=d)$.	—	$a, a+d, a+2d, a+3d, a+4d, \dots$
$(d=2)$.	—	$1, 4, 7, 10, 13, \dots$
$(d=\frac{1}{2})$.	—	$-2.5, -2, -1.5, -1, -.5, \dots$

Descending:

$(d=-d)$.	—	$a, a-d, a-2d, a-3d, a-4d, \dots$
$(d=-2)$.	—	$7, 5, 3, 1, -1, \dots$
$(d=-\frac{1}{2})$.	—	$\frac{3}{2}, \frac{1}{2}, 0, -\frac{1}{2}, -1, \dots$

are arithmetical series.

As the difference is constant, any arithmetical series may be represented by the equation of a straight line—

$y = mx + c$, in the language of Analytic Geometry;

or $s = d(n-1) + a$, in the language of Arithmetical Progression;

in which $c = a$ = the value of the first term (placed at axis $Y-Y$);

$m = d$ = the common difference, + or -, between adjacent terms;

$x = n-1$ = the number of any term considered from (not counting) the first term;

$y = s$ = the value of any term $x = n-1$;

n = the number of any term, counting the first term.

Fig. 5 illustrates an ascending series, and when the first term is a positive quantity. The equation, however, holds good for any case by using the quantities algebraically.

Problem 1.—Find the number of the term whose value is 10, in a series whose common difference is $\frac{1}{2}$ and whose first term is 2.

Fig. 5.

Solution.—From $y = mx + c$ there is obtained,

$$10 = \frac{1}{2}x + 2.$$

$$\therefore x = 16 = n - 1,$$

$$\text{or } n = 17. \text{ Ans.}$$

Problem 2.—Insert 4 terms between the numbers 3 and 28 and find the common difference.

Solution.—From $y = mx + c$

$$28 = m \cdot 5 + 3 \text{ (If 4 terms are inserted, } 28 = 6\text{th term)}$$

$$\therefore x = 5.)$$

$$\text{whence } m = \frac{28-3}{5} = 5 = \text{common difference. Ans.}$$

An arithmetical mean between two quantities = one-half their sum.

Geometrical Progression.—A geometrical series or progression consists of a series of terms which increase or decrease by a common constant factor, f . Thus,

Ascending:

$$(f = r). \quad a, ar, ar^2, ar^3, ar^4, \dots;$$

$$(f = 2). \quad 3, 6, 12, 24, 48, \dots;$$

are geometrical series.

Descending:

$$\left(f = \frac{1}{r}\right). \quad a, \frac{a}{r}, \frac{a}{r^2}, \frac{a}{r^3}, \frac{a}{r^4}, \dots;$$

$$(f = \frac{1}{2}). \quad 4, 2, 1, \frac{1}{2}, \frac{1}{4}, \dots;$$

Any geometrical progression may be represented by a curve whose equation is—

$y = c f^x$, in the language of Analytic Geometry;

or $s = a f^{(n-1)}$, in the language of Geometrical Progression;

in which, $c = a =$ the value of the first term (placed at axis $Y - Y'$);

$f =$ the common factor or ratio between the adjacent terms;

$x = n - 1 =$ number of any term considered *from* (not including) the first term;

$y = s =$ the value of any term $x = n - 1$;

$n =$ the number of any term, counting the first term.

Fig. 6.

Fig. 6 illustrates an increasing series, and when the first term is a positive quantity; but by using the quantities algebraically, the equation holds good for any case.

Problem 1.—Find the value of the 6th term of an increasing series whose 1st term is 3, and the common factor 2.

Solution.—From

$y = c f^x$, there is obtained,

$$y (= s) = 3 \times 2^5 = 3 \times 32. \quad (x = n - 1 = 5.)$$

$\therefore s = 96.$ Ans.

Problem 2.—Insert 3 terms between the numbers 2 and $10\frac{1}{2}$, and find the common factor.

Solution.—From $y = c f^x$ there is obtained.

$10\frac{1}{2} = 2 f^4$ (If 3 terms are inserted, $10\frac{1}{2} = 4$ th term)

$$\therefore x = 4.)$$

$$f^4 = \frac{10\frac{1}{2}}{2} = 5\frac{1}{4} = \frac{21}{4}$$

$$\therefore f = \sqrt[4]{\frac{21}{4}} = 1\frac{1}{2}. \text{ Ans.}$$

Note.—The latter part of the above solution may also be performed by logarithms. Thus,

$$f^4 = \frac{10\frac{1}{2}}{2} = 5.0625 \quad \log 5.0625 = 0.704365 \quad (\text{Divide this by 4.})$$

$$\text{Ans. } f = 1.5 \quad 0.176091 \quad (\text{Find number corresponding.})$$

A geometrical mean between two numbers = the square root of their product (see Fig. 3, page 56).

Compound interest is a good illustration of geometrical progression.

PERCENTAGE, INTEREST AND DISCOUNT.

Percentage.—*Per cent* means *hundredths*, and *rate per cent* means *any given number of hundredths*. Thus, 5 per cent, or 5%, means .05, or $\frac{5}{100}$, in which 5 is the rate. It may also be expressed in true ratio, 5 : 100, meaning 5 parts of the 100, both terms being of the same denomination.

To reduce any rate, expressed in two denominations, to a rate per cent, one term must first be reduced to the denomination of the other so that a true ratio may be expressed. Thus, a rate of grade in feet per mile, as 52 $\frac{1}{2}$ feet per mile, may be expressed in ratio 52 $\frac{1}{2}$: 5280, as there are 5280 feet in a mile. Clearly, this is equal to a $\frac{1}{100}$, or 1% grade.

Simple Interest is percentage in which the element of *time* has to be considered. The sum placed at interest is called the *principal*, and the principal plus the interest is called the *amount*. Simple interest differs from compound interest in that the principal is not allowed to increase from time to time by its own interest.

The rate of interest is the rate per cent for one year. There are two methods used in calculating interest:

(a.) The common method, in which a year is considered to be divided into 12 months of 30 days each.

(b.) The exact method, in which the year is divided into 365 (or 366 if leap year) days.

In either case,

$$\text{Simple Interest} = \text{Principal } (\$) \times \text{Rate } \% \times \text{Time (years).}$$

The Common Method.—Table 1, page 60, shows the simple interest on various principals (\$1.-- \$1,000.) at various rates (34% -- 7%) for time in days and months up to one year. Clearly, by combination and factoring, the interest on any principal, at any rate and for any time, may readily be obtained. Thus, the interest on \$1253. at 4% for 5 months, 11 days, is calculated as follows:

	5 mos.	10d.	1d.
Interest on \$1000 (1000×1)	= 18.75	1.25	
200 (200×1)	= 3.75	.25	
50 (50×1)	= .938	.062	
3	= .056	.004	
Therefore, total interest	= 23.494	+ 1.566	+ .157 = \$25.22. Ans.

This may be calculated in the ordinary manner, as follows:

$$\text{Interest} = 1253 \times .045 \times \frac{51\frac{1}{2}}{12} = \$25.22. \text{ Ans.}$$

As the interest on any amount is directly proportional to the rate, some prefer to use a round rate like 6%. 6 being a factor of 12 (months) and of 30 (days), for a first result, and then factor this result for the required rate. Thus, in the above,

$$\begin{aligned} \text{Interest on } \$1253 \text{ at } 6\% \text{ for } 5 \text{ mos.} &= 1253 \times 2\frac{1}{2}\% = \begin{cases} 12.53 \\ 12.53 \\ 6.265 \end{cases} \\ \text{" " " " } 10 \text{ days} &= 1253 \times \frac{1}{3}\% = 2.089 \\ \text{" " " " } 1 \text{ " } &= \frac{1}{30} \text{ above} = .209 \\ &\text{At } 6\% \quad 33.62 \\ &\text{Deduct } \frac{1}{3} \quad 8.40 \\ &\text{At } 4\frac{1}{3}\%. \quad \$25.22 \text{ Ans.} \end{aligned}$$

The Exact Method.—This is used by various large financial concerns in dealing with each other and where large amounts are involved. The time is the ratio of the number of days for which the principal has been loaned, to the number of days in the year. Thus, if the loan is for 21/ days the time will be $\frac{217}{365}$ of a year; or, if the 29th of February is included, it will be $\frac{217}{366}$ of a year.

Table 2, page 61, gives the number of days from one date to another covering a period of two ordinary years of 365 days each. If one of the years is a leap year add one day to each number of days after February 28th. Thus, if the interest is to be calculated from February 15th of one year to January 10th of the following year, the time would be $\frac{375 - 46}{365} = \frac{329}{365}$ of a year.

If the first year is a leap year the time would be $\frac{330}{366}$ of a year, adding *one* to each term of the ratio. For example, the interest on \$450. from Feb. 15, 1908, (leap year) to Jan. 10, 1909, at 5% = $\$450. \times .05 \times \frac{330}{366} = \29.29 . Ans.

Discount.—The fundamental principle of discount is "money off for cash," but most mercantile houses will discount their trade catalogue prices to their regular customers on short time payments.

A certain customer may be favored with a discount of 20%, which means that the cost to him will be 80% of the catalogue price; another customer, more favored or on account of heavier purchases, may receive a discount of "20 and 10%", making the cost $.80 \times .90 = 72\%$ of the list price; while a third may receive a discount of "20, 10 and 5" which would make the cost $.80 \times .90 \times .95 = 68\frac{4}{10}\%$.

Bank discount is the equivalent interest on the *face* of a note up to the time of its maturity.

True discount is the equivalent interest on the present worth of a note, or principal which, at maturity, will amount to the face of the note. Thus, Present worth + interest on same (= true discount) = \$1 + interest on same;

$$\text{Amount (= face of note)} = \text{Face of note} \quad \text{Amount of \$1 and int.}$$

$$\text{Or, present worth} = \frac{\text{Amount of \$1 and interest, to maturity}}{\text{Face of note}}$$

Whence the true discount = face of note - present worth.

Compound Interest.—The simple interest on any principal loaned is due annually. But by a special agreement it may become due semi-annually, quarterly, or for any other period. If not paid, it is added periodically to

the principal for a new principal drawing interest; hence, compound interest. (See Table 3, page 62.)

The amount (principal and interest) due at the end of any number of years, n , interest payable annually, may be expressed as follows:

$$\text{Amount} = \text{Principal} (1 + \text{Rate } \%)^n.$$

If the number of years is large the result is easily obtained by the use of logarithms. Further, the above formula may represent any general case by considering n the number of periods (as semi-annual or quarterly periods) of compounding — the proportionate rate per cent to be used for that period.

* Note that all repeating decimals may be extended indefinitely. Thus, the interest on \$1.00 at 4% for 4 months is given as .013³ or 1½ cents, because the decimal .013³ = .0133333...; hence the interest on \$1,000,000, at the same rate and for the same time, is \$13,333.33½. Decimals which are not repeating decimals are exact.

Example.—Find the amount of \$600. compounded at 2% semi-annually for 6 years (12 periods).

Solution.
 $\log. 600. = 2.7781513$
 $12 \times \log. 1.02 = 0.1032024$

Ans. \$760.95 . . . 2.8813537

Clearly, the process of calculating compound interest is simply geometrical progression, in which $1 + \text{Rate } \%$ is a constant factor between successive terms.

EQUATION OF PAYMENTS.

Like Alligation, this is a "center of gravity" problem. It consists in finding the average time when a single payment can be made to cancel several notes, bearing the same rate of interest, which fall due on different dates.

Problem.—A holds B's notes as follows: \$600 due in 1 month; \$700 due in 3 months; \$400 due in 4 months; and \$300 due in 5 months—all bearing the same rate of interest. At what time can B make a single payment of the whole amount, \$2000, to cancel the obligation equitably?

Solution.—
 $600 \times 1 = 600.$
 $700 \times 3 = 2100.$
 $400 \times 4 = 1600.$
 $300 \times 5 = 1500.$

$2000 \times x = 5800.$

$\therefore \text{Average time } x = \frac{5800}{2000} = 2.9 \text{ months} = 2 \text{ m., } 27 \text{ d. Ans.}$

* Periods may be annual, semi-annual or quarterly, etc. Periodic rates are proportioned to the length of the period. Thus, 4% annual = 2% semi-annual rate. For explanation of table, see top of page 60.

PARTIAL PAYMENTS.

In cancelling notes by partial payments the following is the rule in United States law:

Whenever the payment or payments *equal or exceed* the interest a new principal shall be formed by adding the interest and deducting the payment or payments. That is, the principal cannot be reduced without first cancelling the interest.

A common method, however, is to consider the debt as the original principal together with its accumulated interest down to the date of settlement; this to be cancelled by the various payments (considered as separate principals) together with their accumulated interest, down to the same date.

ANNUITIES.

Specified payment of money amounting to a fixed sum each year is called an annuity:—*Certain annuity*, when payments extend over certain definite periods; *Contingent annuity*, when payments are contingent on certain events; *Life annuity*, when payments are for life of one or more persons; *Deferred annuity*, when payments begin at some future time or event.

The value of an annuity may be reduced to its —

Final Value, or amount of all payments at compound interest to the end of the annuity;

Initial value, or equivalent principal which, at compound interest for the life of the annuity, would amount to its final value;

Present value, or equivalent principal which, at compound interest for the balance of the life of the annuity, would amount to the value of future payments at compound interest to the end of the annuity.

The fundamental equations which enter into the conversion of annuity in one form to its equivalent in another form, are those of geometrical progression, in general, and compound interest in particular.

Final Value of Annuity.—The final value of an annuity is directly proportional to the value of the annual payment. Hence, from a table calculated on the basis of an annuity of \$1, at different rates of interest and for any number of years, the final value of any annuity at the same rate and for the same time may be obtained by multiplying the value in the table by the annuity.

Table 4, following, gives the final values of an annuity of \$1 at compound interest rates of 2, 3, 3½, 4, 4½, 5, 6 and 7 per cent up to 50 years. It is calculated from the formula:

$$\text{Final value} = \frac{(1 + \text{Rate } \%)^x - 1}{\text{Rate } \%}$$

in which x = the number of years = the number of payments, the final value being calculated up to the time of each payment, and also includes that payment.

Present or Initial Value of Annuity.—The present value of an annuity may be considered the *initial* value of that part of the annuity comprising future payments, the date beginning with the first of these payments. Hence the term "Present value" will be used in the broadest sense. Further, it is the amount of capital or the principal which, if placed at interest, would exactly furnish the annuities for the specified time; that is, the principal would be depleted at the end of that time.

For the same time and at the same rate of interest, the present value is directly proportional to the annuity (and to the final value). Hence, in Table 5, page 65, to find the present value of any annuity, as \$1000, multiply the tabular number by that annuity (1000). The table is calculated from the formula:

$$\text{Present value} = \frac{1 - \frac{1}{(1 + \text{Rate } \%)^x}}{\text{Rate } \%}$$

in which x = the number of years to run = the number of payments to be made, payments being made at the end of each year.

Sinking Fund.—An annuity may be applied as a sinking fund to cancel a debt payable at some future time, as in the case of bonds maturing in, say, 20, 30 or 50 years. A plant may thus be made to pay for itself by

4.—FINAL VALUE OF ANNUITY OF \$1 IN FROM 1 TO 50 YEARS OR PERIODS.

annually setting aside a certain amount of its earnings to be placed at compound interest.

Table 6, page 65, shows the annual amount to be set aside in order to accumulate \$1000 at various rates of interest and for various terms of years, compounded annually. It is calculated from the formula:

$$\text{Annuity} = 1000 \left(\frac{\text{Rate } \%}{(1 + \text{Rate } \%)^x - 1} \right);$$

in which x = the number of years = the number of annuities, the payments being made at the end of each year.

Problem.—What semi-annual payments shall be made to a sinking fund to create \$1,000,000 in 20 years, interest at 4%?

Solution.—In this case there will be 40 periods compounded at 2%. From the table, 40 payments of \$16.556 will create \$1,000. But, in order to create \$1,000,000 this must be multiplied by 1000 $\left(= \frac{1,000,000}{1000} \right)$. Hence the semi-annual payments would be \$16,556 each.

4.—MEASURES, WEIGHTS AND MONEY.

FUNDAMENTAL UNITS.

The Metric System, on account of its simplicity, is destined in all probability to become the international standard of weights and measures. It has been legalized by Great Britain, Russia and the United States; and has been adopted by all other European nations, by Mexico, and by many South American States.

Meter.—*Length, Area, Volume.* The international standard Meter, the unit of length, is the distance between two lines on a platinum-iridium bar, at 0° centigrade, deposited at the International Bureau of Weights and Measures, in Paris. The legalized ratio of the standard meter to the standard

yard by the United States* is $\frac{39.37}{36.00} = 1.09361111\text{---} = \dagger 1.09361\text{'}1$; hence, the following equivalents:

LENGTH.

1 meter = 1.09361'1 yards = 3.28083'3 feet = 39.37 inches.
 1 yard = 0.914 401 828 80 meter. Log = 9.9611371. Co-log = 0.0388629
 1 foot = 0.304 800 609 60 meter. " = 9.4840158. " = 0.5159842
 1 inch = 0.025 400 050 80 meter. " = 8.4048346. " = 1.5951654

AREA.

1 square meter = 1.195 985 262 35 sq. yd. = 10.763 867 361'1 sq. ft. =
 1549.9969 sq. ins.
 1 sq. yd. = 0.836 130 704 52 sq. met. Log = 9.9222742. Co-log = 0.0777258
 1 sq. ft. = 0.092 903 411 61 sq. met. " = 8.9680316. " = 1.0319684
 1 sq. in. = 0.000 645 162 58 sq. met. " = 6.8096692. " = 3.1903308

VOLUME.

1 cubic meter = 1.307 942 771 63 cu. yd. = 35.314 454 833 91 cu. ft. =
 61023.377953 cu. ins.
 1 cu. yd. = 0.764 559 445 33 cu. met. Log = 9.8834113. Co-log = 0.1165887
 1 cu. ft. = 0.028 317 016 49 cu. met. " = 8.4520475. " = 1.5479525
 1 cu. in. = 0.000 016 387 16 cu. met. " = 5.2145038. " = 4.7854962

Liter.—*Capacity (Liquid and Dry).* The liter, the unit of capacity, is the volume of one kilogram of pure water at its maximum density; and this is equal to a cubic decimeter, or a cube whose edge is one-tenth of a meter = 3.937 inches. The capacity of one liter is therefore $\frac{1}{1000}$ of the volume of a cubic meter. The following are the United States† equivalents:

*In Great Britain the meter has been legalized at 39.37079 inches, but the length of 39.370432 inches, as adopted by France, Germany, Belgium and Russia, is frequently used.

† Logarithm $1.09361\text{'}1 = 0.0388629$; co-logarithm = 9.9611371.

‡ The Imperial gallon, the British unit of *liquid* capacity, contains 277.274 cubic inches, or $1.200320 \left(= \frac{277.274}{231} \right)$ United States gallons. The Imperial bushel, the British unit of *dry* capacity, contains 8 Imperial gallons or 2218.192 cubic inches = $1.03151570 \left(= \frac{2218.192}{2150.42} \right)$ United States (struck) bushels. British measures of the same denomination as those of the United States are hence greater than the latter by these ratios.

VOLUME.

1 liter = 1 cubic decimeter = 0.001 cubic meter.

MASS.

1 liter (= 1 cubic decimeter) of pure water at maximum density weighs 1 kilogram (kilo).

1 millimeter (= 1 cubic centimeter) of pure water at maximum density weighs 1 gram.

Gram.—Mass (Weight). The Gram, the unit of weight, is the weight of a cubic centimeter (1 millimeter) of pure water at its maximum density $\frac{1}{1000}$ of the international kilogram. The bureau of Standards, Washington, D. C., gives the fundamental equivalents:

1 avoirdupois pound = 453.592 4277 grams, and Log = 2.6566658
 1 troy pound = ~~453~~ 453.592 4277 avoirdupois pound = 373.241 769 078 857 142 $8\frac{5}{8}$ grams, from which are derived the following values: Log = 2.5719903

1 kilogram	— 2.204 622 341 406 avoirdupois pounds.	Log = 0.3433342
	— 2.679 228 539 903 troy pounds.	" — 0.4280097

3 miles (= 24 furs. = 960 rds. = 5280 yds. = 15840 ft.).....	=	1 league	=	4828.042 "

3.—SURVEYORS' MEASURE (LINEAL).

7.92 inches.....	=	1 link	=	.2011684 Meters
100 links (= 4 rds. = 22 yds. = 66 ft.).....	=	1 chain	=	20.11684 "
80 chains (320 rds. = 1760 yds. = 5280 ft.).....	=	1 statute mile	=	1609.347 "

4.—*MARINERS' MEASURE.

6 feet.....	=	1 fathom	=	1.828804 Meters
120 fathoms (= 720 ft.).....	=	1 cable length	=	219.4564 "
[7½ cable lengths (= 880 fathoms = 5280 ft.).....]	=	1 statute mile	=	1609.347 "
1.15246 statute miles (= 6085 ft.).....	=	1 nautical mile	=	1854.712 "
60 nautical miles = 1 degree.	360 degrees = circumference of the earth.			

* The old nautical mile was given as 7½ cable lengths = 5400 feet, but it is now obsolete. The present nautical mile is not an exact term, being equal to about one minute of longitude at the equator. The British Admiralty knot is 6080 ft. The nautical mile of the U. S. Coast Survey is 6086.07 ft. = 1.152664 statute or land miles. Three nautical miles = 1 league.

5.—LENGTHS—INCHES AND MILLIMETERS.—EQUIVALENTS OF DECIMAL AND COMMON FRACTIONS OF AN INCH IN MILLIMETERS.

9 square feet.....	= 1 square yard	= 0.836131 sq. meter.
30 $\frac{1}{2}$ square yards (= 272 $\frac{1}{2}$ sq. ft.).....	= 1 square rod	= 25.292954 sq. meters.
40 square rods (= 1210 sq. yds. = 10890 sq. ft.).....	= 1 rood	= 0.1011718 hectares.
4 roods (= 160 sq. rods = 4840 sq. yds. = 43560 sq. ft.).....	= 1 acre	= 0.4046873 hectares.
640 acres (= 3,097,600 sq. yds. = 27,878,400 sq. ft.).....	= 1 square mile	= 258.99985 hectares.
36 square miles (= 23040 acres = 1,003,622,400 sq. ft.).....	= 1 township	= 9323.9945 hectares.

15.—TEXAS LAND MEASURE.

(Also used in Mexico, New Mexico, Arizona and California.)

26,000,000	sq. varas (sq. of 5,099	varas) = 1 league and 1 labor	= 4,605.5 acres.
1,000,000	sq. varas (sq. of 1,000	varas) = 1 labor	= 177.136 acres.
25,000,000	sq. varas (sq. of 5,000	varas) = 1 league	= 4,428.4 acres.
12,500,000	sq. varas (sq. of 3,535.5	varas) = $\frac{1}{2}$ league	= 2,214.2 acres.
8,333,333	sq. varas (sq. of 2,886.7	varas) = $\frac{1}{3}$ league	= 1,476.13 acres.
6,250,000	sq. varas (sq. of 2,500	varas) = $\frac{1}{4}$ league	= 1,107.1 acres.
7,225,000	sq. varas (sq. of 2,688	varas)	= 1,280 acres.
3,612,800	sq. varas (sq. of 1,900.8	varas) = 1 section	= 640 acres.
1,806,400	sq. varas (sq. of 1,344	varas) = $\frac{1}{2}$ section	= 320 acres.
963,200	sq. varas (sq. of 950.44	varas) = $\frac{1}{4}$ section	= 160 acres.
451,600	sq. varas (sq. of 672	varas) = $\frac{1}{8}$ section	= 80 acres.
225,800	sq. varas (sq. of 475	varas) = 1.16 section	= 40 acres.
5,645.376	sq. varas (sq. of 75.137	varas) = 4,840 sq. yd.	= 1 acre.

To find the number of acres in any number of square varas, multiply the latter by 177 (or to be more exact, by 177 $\frac{1}{4}$), and cut off six decimals.

1 vara = 33 $\frac{1}{8}$ inches

1,900.8 varas = 1 mile

16.—WEIGHTS AND MEASURES OF THE PHILIPPINES.

1 pulgada (12 líneas) = .927 inches.	1 libra (16 onso) = 1.0144 lb. av.
1 pie = 11.125 inches.	1 arroba = 25.360 lb. av.

Note.—1 electric horse-power = 1 kilowatt = 1000 watts = 1000 joules per second.

1 metric horse-power = 75 meter-kilograms per second.

Examples to illustrate the use of above table:

8 meter-kilograms = 8×9.81 joules. 10 British thermal units = 10×778 ft.-lbs.

*.0637675 = .000 000 37675; .0637³ = .000 003 703 7037—; etc.

35.—ELECTRICAL, MECHANICAL AND HEAT UNITS—EQUIVALENT VALUES.

(See also preceding table.)

1 Foot-pound

- = 1.356284 joules.
- = 0.138255 kilogram-meters.
- = 0.0000037675 kilowatt hours.
- = 0.0012853 heat units.
- = 0.0000005705 horse-power hour.

1 Kilogram-meter

- = 9.81 joules.
- = 7.23300 ft.-lbs.
- = 0.0000036530 horse-power hour.
- = 0.0000027250 kilowatt hour.
- = 0.0092969 heat units.

1 Joule

- = 0.737308 ft.-lbs.
- = 0.101937 kilogram-meters.
- = 0.000947697 heat units.
- = 1 watt second.
- = 0.000002777 kilowatt hour.
- = 0.000000372378 horse-power hour.

1 Heat Unit (B.T.U.)

- = 1055.18932 joules.
- = 1055.18932 watt-seconds.
- = 778 ft.-lbs.
- = 107.5426 kilogram-meters.
- = 0.00029311 kilowatt hour.
- = 0.00039293 horse-power hour.
- = 0.0000688 lb. carbon oxidized.*
- = 0.001036 lb. water evaporated from and at 212° F.*

1 Watt

- = 1 joule per second.
- = 0.00134056 horse power.
- = 3.411711 heat units per hour.
- = 0.737308 ft.-lb. per second.
- = 0.0035 lb. water evaporated per hour.*
- = 44.23851 ft.-lbs. per minute.
- = 0.00135916 metric horse power.

1 Kilowatt

- = 1000 watts.
- = 1.34056 horse power.
- = 2654311 ft.-lbs. per hour.
- = 44.23851 ft.-lbs. per minute.
- = 737.308 ft.-lbs. per second.
- = 3411.711 heat units per hour.
- = 56.86185 heat units per minute.
- = 0.9476975 heat units per second.
- = 0.2275 lb. carbon oxidized per hour.*
- = 3.53 lbs. water evaporated per hour from and at 212° F.*

1 Watt Per Square Inch

- = 8.19 heat units per sq. ft. per min.*
- = 6371 ft.-lbs. per sq. ft. per min.*
- = 0.193 horse power per sq. ft.*

1 Kilowatt-hour

- = 1000 watt-hours.
- = 1.34056 horse-power hours.
- = 2654311 ft.-lbs.
- = 3600000 joules.
- = 3411.711 heat units.
- = 366972.5 kilogram-meters.
- = 0.235 lb. carbon oxidized with perfect efficiency.
- = 3.53 lbs. water evaporated from and at 212° F.*
- = 22.75 lbs. of water raised from 62° to 212° F.*

1 Horse Power

- = 745.9566 watts.
- = 0.7459566 kilowatts.
- = 550 ft.-lbs. per second.
- = 33000 ft.-lbs. per minute.
- = 2544.987 heat units per hour.
- = 42.41645 heat units per minute.
- = 0.706941 heat units per second.
- = 0.175 lb. carbon oxidized per hour.*
- = 2.64 lbs. water evaporated per hour from and at 212° F.*

1 Horse Power-hour

- = 0.7459566 kilowatt-hours.
- = 1980000 ft.-lbs.
- = 2544.987 heat units.
- = 273745.5 kilogram-meters.
- = 0.175 lb. carbon oxidized with perfect efficiency.*
- = 2.64 lbs. water evaporated from and at 212° F.*
- = 17.0 lbs. water raised from 62° to 212° F.*

1 Lb. Carbon Oxidized with Perfect Efficiency*

- = 1.11 lb. Anthracite coal oxidized.
- = 2.5 lbs. dry wood oxidized.
- = 21 cubic feet illuminating gas.
- = 4.26 kilowatt-hours.
- = 5.71 horse-power hours.
- = 11315000 ft.-lbs.
- = 15 lbs. water evaporated from and at 212° F.*
- = 14544 heat units.

1 Lb. Water Evaporated from and at 212° F.*

- = 0.283 kilowatt-hour.
- = 0.379 horse-power hour.
- = 965.7 heat units.
- = 103900 kilogram-meters.
- = 1019000 joules.
- = 751300 ft.-lbs.
- = 0.0664 lb. of carbon oxidized.

1 Heat Unit per square ft. per min.*

- = 0.122 watt per square inch.
- = 0.0176 kilowatt per sq. ft.
- = 0.0236 horse power per sq. ft.

* Values by H. W. Leonard.—See The Electrical Engineer, Feb. 25, 1895.

36.—FOREIGN WEIGHTS AND MEASURES.
(Compiled by the Department of State.)

Denominations.	Where Used.	American Equivalents.	Denominations.	Where Used.	American Equivalents.
Almude	Portugal	4. 422 gallons.	Catty	Japan	1. 31 pounds.
Ardeb	Egypt	7. 697 bushels.	do	Java, Siam and Malacca	1. 35 pounds.
Are	Metric	0. 02471 acre.	do	Sumatra	2. 12 pounds.
Arabe	Paraguay	25 pounds.	Centaro	Central America	4. 2631 gallons.

Numbers.

37.—ABSTRACT NUMBERS.

10 units.....	= 1 ten.....	=	10
10 tens.....	= 1 hundred.....	=	100
10 hundreds.....	= 1 thousand.....	=	1 000
10 thousands.....	= 1 ten thousand.....	=	10 000
10 ten thousands.....	= 1 hundred thousand.....	=	100 000
10 hundred thousand.....	= 1 million.....	=	1 000 000

A pure decimal, where the first significant figure is far removed from the decimal point, may be abbreviated by a subscript to the first cipher to indicate the number of ciphers at the right of the decimal point and to the left of the first significant figure. Thus,

2 millionths,	or .000002,	may be written, .0 ₅ 2.
65 hundred millionths,	or .00000065,	may be written, .0 ₆ 65.
4 billionths,	or .000000004,	may be written, .0 ₈ 4.

38.—DUODECIMO NUMBERS.

12 units = 1 dozen.	
12 dozen = 1 gross = 144.	(20 units = 1 score.)
12 gross = 1 great gross = 1728.	

39.—PAPER.

24 sheets = 1 quire.	2 reams = 1 bundle = 960.
20 quires = 1 ream = 480.	5 bundles = 1 bale = 4800.

Money.

40.—UNITED STATES MONEY.

10 mills (m) = 1 cent (ct.)	(Unit is \$1.)
10 cents = 1 dime (d.)	10 dollars = 1 eagle (E.)
10 dimes = 1 dollar (\$.)	2 eagles = 1 double eagle (EE.)

41.—FOREIGN MONEY.

English Money: 4 farthings (far.) = 1 penny (d.); 12 pence = 1 shilling (s.); 20 shillings = 1 pound (£) = 1 sovereign (= \$4.8665, U. S. money).
 1 guinea = 21 shillings; 1 crown = 5 shillings; 1 florin = 2 shillings.
French Money: 10 centimes = 1 decime; 10 decimes = 1 franc (fr.) (= \$0.193, U. S. money).
German Money: 100 pfennig = 1 mark (= \$0.238, U. S. money).
Italian Money: 100 centesimi = 1 lira (= \$0.193, U. S. money).
Russian Money: 100 copecks = 1 ruble (= \$0.515, U. S. money).
Austro-Hungarian Money: 100 kreutzers = 1 florin.

42.—VALUE OF FOREIGN COINS IN UNITED STATES MONEY. (Proclaimed by the Secretary of the Treasury, October 1, 1905.*)

Country.	Standard.	Monetary Unit.	Value in U. S. Gold Dollar.	Coins.
Argent. R.	Gold.	Peso.	\$0.96.5	Gold: Argentine (\$4.82.4) and $\frac{1}{2}$ Argentine. Silver, peso and divisions.
Austria-H.	Gold.	Crown.	20.3	Gold: 10 and 20 crowns. Silver: 1 and 5 crowns.
Belgium.	Gold.	Franc.	19.3	Gold: 10 and 20 francs. Silver: 5 francs.
Bolivia.	Silver.	Boliviano.	44.1	Silver: boliviano and divisions.
Brasil.	Gold.	Milreis.	54.6	Gold: 5, 10, and 20 milreis. Silver: $\frac{1}{2}$, 1, and 2 milreis.
Canada.	Gold.	Dollar.	1.00	Silver: peso and divisions.
Cent. Am.	Silver.	Peso†.	44.1	Gold: escudo (\$1.82.5), doubloon (\$3.65), and condor (\$7.30). Silver: peso and divisions.
Chile.	Gold.	Peso.	36.5	
		Shanghai	66.1	
China.	Silver.	Tael.	73.6	
		Hankwan	72.3	
		Canton.	72.3	
Colombia.	Gold.	Dollar.	1.00	Gold: condor (\$9.64.7) and double-condor. Silver: peso.
Costa Rica.	Gold.	Colon.	46.5	Gold: 2, 5, 10, and 20 colons (\$9.30.7). Silver: 5, 10, 25, and 50 centimos.
Denmark.	Gold.	Crown.	26.8	Gold: 10 and 20 crowns.
Ecuador.	Gold.	Sucres.	48.7	Gold: 10 sucres (\$4.86.65). Silver: sucre and divisions.
Egypt.	Gold.	Pound (100 piasters).	4.94.3	Gold: pound (100 piasters), 5, 10, 20, and 50 piasters. Silver: 1, 2, 5, 10, and 20 piasters.
France.	Gold.	Franc.	19.3	Gold: 5, 10, 20, 50, and 100 frs. Silver: 5 frs.
Germany.	Gold.	Mark.	23.8	Gold: 5, 10, and 20 marks.
Gt. Britain.	Gold.	Pound sterling.	4.86.6†	Gold: sovereign (pound sterling) and $\frac{1}{2}$ sovereign.
Greece.	Gold.	Drachma.	19.3	Gold: 5, 10, 20, 50, and 100 drachmas. Silver: 5 drachmas.
Haiti.	Gold.	Gourde.	96.5	Gold: 1, 2, 5, and 10 gourdes. Silver: gourde and divisions.
India.	Gold.	Pound sterling‡.	4.86.6†	Gold: sov. (\$4.86.65). Silver: rupee and divisions.
Italy.	Gold.	Lira.	19.3	Gold: 5, 10, 20, 50, and 100 lire. Silver: 5 lire.
Japan.	Gold.	Yen.	49.8	Gold: 1, 2, 5, 10, and 20 yen. Silver: 10, 20, and 50 sen.
Mexico.	Gold.	Peso ‡	49.8	Gold: 5 and 10 pesos. Silver: dollar (or peso)** and divisions.
Neth'lands.	Gold.	Florin.	40.2	Gold: 10 florins. Silver: $\frac{1}{2}$, 1, and 2 $\frac{1}{2}$ florins.
N'found'ld.	Gold.	Dollar.	1.01.4	Gold: 2 dollars (\$2.02.7).
Norway.	Gold.	Crown.	26.8	Gold: 10 and 20 crowns.
Panama.	Gold.	Balboa.	1.00.0	Gold: 1, 2 $\frac{1}{2}$, 5, 10, and 20 balboas. Silver: peso and divisions.
Peru.	Gold.	Sol.	48.7	Gold: libra (\$4.86.65). Silver: sol and divisions.
Portugal.	Gold.	Milreis.	1.08	Gold: 1, 2, 5, and 10 milreis.
Russia.	Gold.	Ruble.	51.5	Gold: 5, 7 $\frac{1}{2}$, 10, and 15 rubles.
Spain.	Gold.	Peseta.	19.3	Gold: 25 pesetas. Silver: 5 pesetas.
Sweden.	Gold.	Crown.	26.8	Gold: 10 and 20 crowns.
Switzerland.	Gold.	Franc.	19.3	Gold: 5, 10, 20, 50, and 100 francs. Silver: 5 francs.
Turkey.	Gold.	Piaster.	04.4	Gold: 25, 50, 100, 250, and 500 piasters.
Uruguay.	Gold.	Peso.	1.03.4	Gold: peso. Silver: peso and divisions.
Venezuela.	Gold.	Bolivar.	19.3	Gold: 5, 10, 20, 50, and 100 bolivars. Silver: 5 bolivars.

* The coins of silver-standard countries are valued by their pure silver contents, at the average market price of silver for the three months preceding the date of this circular. † Not including Costa Rica. ‡ The sovereign is the standard coin of India, but the rupee (\$0.44.8) is the

22a.—VALUE OF FOREIGN COINS AND PAPER NOTES IN AMERICAN MONEY
BASED UPON THE VALUES EXPRESSED IN TABLE 42.

Number.	British & Sterling.	German Mark	French Franc, Italian Lira.	Chinese Tael (Hankwan.)	Dutch Florin.	Japanese Yen, Mexican Peso.	Russian Gold Ruble.	Austrian Crown

43.—COMPARISON OF PRICES.

French and German prices for metric units, British prices for Imperial units, and United States prices for United States standard weights and measures.

[Based upon the circular of the Secretary of the Treasury dated October 1, 1902, fixing the legal equivalent of the (German) mark at 23.8 cents, of the (French) franc at 19.3 cents, and the British pound sterling at \$4.8665.]

Miscellaneous.

44.—TIME MEASURE.

60 seconds	1 second (s)	= 15 seconds ($0^{\circ}-00'-15''$) of longitude.
60 minutes (= 3600 seconds)	1 minute (m)	= 15 minutes ($0^{\circ}-15'$) of longitude.
24 hours (= 1440 m = 86400 s)	1 hour (h)	= 15 degrees (15°) of longitude.
7 days (= 168 h = 10080 m = 604800 s)	1 solar day (d)	= 360 degrees (360°) of longitude.
52 weeks (= 365 d = 8760 h = 525600 m)	1 week.	
52 weeks (= 366 d = 8784 h = 527040 m)	1 common year.	
100 years (= 75 common + 25 leap)	1 leap year.	
	1 century.	

45.—CIRCULAR MEASURE.

60 seconds	= 1 second ($^{\circ}$)	= $\frac{1}{15}$ ($.06\bar{6}$) second of time.
60 minutes (= 3600 seconds)	= 1 minute ($'$)	= 4 seconds of time.
30 degrees (= $1800' = 108000''$)	= 1 degree ($^{\circ}$)	= 4 minutes of time.
	= 1 sign	= { the angle at the base of a right triangle whose altitude is 1, hypotenuse 2, and base $\sqrt{3}$.
90 degrees (= $5400' = 324000''$)	= 1 right angle ($\angle$)	= 6 hours of time.
180 degrees (= $10800' = 648000''$)	= 1 semi-circumference	= $\pi = 3.14159265\dots$
360 degrees (= $21600' = 1296000''$)	= 1 circumference	= 2π . radius = π . diameter.

5.—ALGEBRA.

An algebraic equation is a shorthand mathematical expression, and every such expression may be transformed by observing certain algebraic rules. The first letters of the alphabet, $a, b, c, \dots$, represent the known quantities of the equation, and the last letters, x, y, s , the unknown. *Members* of an equation are separated by the sign of equality ($=$); *terms* of a member are separated by plus (+) and minus (−) signs; and *factors* of a term are separated by the signs of multiplication ($\times$) or ($\cdot$), either expressed or understood.

Any *factor* or *set of factors* of a term may be considered the *denomination* of that term. Thus, in $ax\sqrt{y}$, either $a, x, \sqrt{y}, ax, a\sqrt{y}, x\sqrt{y}$ or $ax\sqrt{y}$ may be chosen as the denomination, as may be expedient.

Addition and Subtraction.—Place *like terms* (terms having the same denomination) in the same column, and reduce fractions to a common denominator, before adding or subtracting:

$$\begin{array}{rcl} 4x + 5x^2y + \sqrt{d} + \frac{1}{\sqrt{x}} & \frac{x^2}{a+b} + \frac{y^2}{a+b} = \frac{x^2+y^2}{a+b} \\ -2x + 3x^2y - 2\sqrt{d} + \frac{2}{\sqrt{x}} & \frac{(a+b)^2}{x} - \frac{(a+b)^2}{y} = \frac{(y-x)(a+b)^2}{xy} \\ \text{Sum} = 2x + 8x^2y - \sqrt{d} + \frac{3}{\sqrt{x}} & 3\sqrt{3x} \pm \sqrt{12x} = (3 \pm 2)\sqrt{3x} \\ \text{Diff.} = 6x + 2x^2y - 3\sqrt{d} - \frac{1}{\sqrt{x}} & \end{array}$$

Note.—In subtraction, reverse the + and − signs of the subtrahend and proceed as in addition.

Exponents.—The following hints are given without discussion:

$$\begin{aligned} n \times n \times n &= nnn = nn^2 = n^2n = n^{1+2} = n^{2+1} = n^3 = \frac{1}{n^{-3}} = n^3 = \sqrt[n]{n^3} \\ n \sqrt{xy} &= n\sqrt{x}\sqrt{y} = nx^{\frac{1}{2}}y^{\frac{1}{2}} = \frac{x^{\frac{1}{2}}y^{\frac{1}{2}}}{n^{-1}} = \frac{n}{x^{-\frac{1}{2}}y^{-\frac{1}{2}}} = \sqrt{n^2xy} = (n^2xy)^{\frac{1}{2}} \\ \sqrt[3]{\frac{-8x^3}{27y^3}} &= \frac{\sqrt[3]{-8x^3}}{\sqrt[3]{27y^3}} = \frac{(-8)^{\frac{1}{3}}(x^3)^{\frac{1}{3}}}{(27)^{\frac{1}{3}}(y^3)^{\frac{1}{3}}} = \frac{-2x}{3y} = -\frac{2x}{3y^{\frac{1}{3}}} \\ x^{\frac{1}{2}} &= \sqrt[2]{x^1}, \quad a^{\frac{1}{3}} = \sqrt[3]{a^1}, \quad a^{\frac{x}{n}} = \sqrt[n]{a^x}, \quad n^{-\frac{1}{x}} = \frac{1}{n^{\frac{1}{x}}} = \frac{1}{\sqrt[n]{n^x}}, \quad \left(\frac{a}{x}\right)^n = \frac{a^n}{x^n} \\ x^{n-n} &= x^n x^{-n} = x^0 = \frac{x^n}{x^n} = 1, \quad a^0 = 1, \quad n^0 = 1^* \\ x^n x^n &= x^{n+n} = x^{2n}, \quad a^n a^x = a^{n+x}, \quad a^{n-x} = a^n a^{-x} = \frac{a^n}{a^x}, \\ (x^m)^n &= x^{mn}, \quad (x^3)^5 = x^{30}, \quad (m^x)^{-n} = m^{-nx} = \frac{1}{m^{nx}}, \quad (x^2y^3)^2 = x^4y^6. \end{aligned}$$

*Any number whose exponent is 0, is equal to 1.

Multiplication and Powers.

Monomials: $n^2 \times n^{\frac{1}{2}} = n^2 n^{\frac{1}{2}} = n^{2\frac{1}{2}} = n^{\frac{5}{2}} = \sqrt{n^5} = \frac{n^5}{n^{\frac{1}{2}}}$.

$$a^2 \times a n^2 = a^4 n^2. \quad 2\sqrt{3} \times 3\sqrt{5} = 6\sqrt{15}. \quad 3\sqrt{a} \cdot x \times \sqrt{a} \cdot x = 3ax^2.$$

Like signs give *plus*: $a \times b = ab$.

$$-a \times (-b) = ab.$$

Unlike signs give *minus*: $-a \times b = -ab$.

$$a \times (-b) = -ab.$$

Polynomials: Multiply each term of the multiplicand by each term of the multiplier, placing like terms of the products in "column," and add.

$$\begin{array}{r} a^2 b^3 - a^2 b \\ a b^3 - a^2 b^4 \end{array}$$

$$\begin{array}{r} 3ax^2 + 4\sqrt{5} \\ \sqrt{5} \end{array}$$

$$\begin{array}{r} -a^2 b^4 + a^4 b^3 \\ a^2 b^5 - a^2 b^4 \end{array}$$

$$\text{Product} = 3ax^2\sqrt{5} + 20$$

$$\begin{aligned} \text{Product} &= a^2 b^5 - 2a^2 b^4 + a^4 b^3 \\ &= a^2 (b^5 - 2ab^4 + a^2 b^3). \\ &= a^2 b^3 (b - a)^2. \end{aligned}$$

$\left. \begin{array}{l} (x \pm y)^2 = x^2 \pm 2xy + y^2 \\ (x+y)(x-y) = x^2 - y^2 \end{array} \right\}$ These two formulas are the foundation of many short methods in arithmetic. (See page 11).

$$(x \pm y)^3 = x^3 \pm 3x^2y + 3xy^2 \pm y^3.$$

$$(x+y)(x^2 - xy + y^2) = x^3 + y^3.$$

$$(x-y)(x^2 + xy + y^2) = x^3 - y^3.$$

$$(x+y+s)^2 = x^2 + y^2 + s^2 + 2xy + 2xs + 2ys.$$

$$(x+y+s)^3 = x^3 + y^3 + s^3 + 3x^2(y+s) + 3y^2(x+s) + 3s^2(x+y) + 6xys.$$

Binomial formula for expanding the sum or difference of two numbers, to any power:

$$(a \pm x)^n = a^n \pm na^{n-1}x + \frac{n(n-1)}{1 \times 2} a^{n-2}x^2 \pm \frac{n(n-1)(n-2)}{1 \times 2 \times 3} a^{n-3}x^3 + \dots$$

$$\text{Thus: } (a+x)^5 = a^5 + 5a^4x + \frac{5 \times 4}{1 \times 2} a^3x^2 + \frac{5 \times 4 \times 3}{1 \times 2 \times 3} a^2x^3 + \frac{5 \times 4 \times 3 \times 2}{1 \times 2 \times 3 \times 4} ax^4 +$$

$$\frac{5 \times 4 \times 3 \times 2 \times 1}{1 \times 2 \times 3 \times 4 \times 5} x^5$$

$$= a^5 + 5a^4x + 10a^3x^2 + 10a^2x^3 + 5ax^4 + x^5.$$

$$(a+x)^{\frac{1}{2}} = a^{\frac{1}{2}} + \frac{1}{2}a^{-\frac{1}{2}}x + \frac{\frac{1}{2}(-\frac{1}{2})}{1 \times 2} a^{-\frac{3}{2}}x^2 + \frac{\frac{1}{2}(-\frac{1}{2})(-\frac{3}{2})}{1 \times 2 \times 3} a^{-\frac{5}{2}}x^3 +$$

$$\frac{\frac{1}{2}(-\frac{1}{2})(-\frac{3}{2})(-\frac{5}{2})}{1 \times 2 \times 3 \times 4} a^{-\frac{7}{2}}x^4 \dots\dots$$

$$= a^{\frac{1}{2}} + \frac{x}{2\sqrt{a}} - \frac{x^2}{2 \times 2^{\frac{1}{2}}\sqrt{a^3}} + \frac{3x^3}{2 \times 3 \times 2^{\frac{3}{2}}\sqrt{a^5}} - \frac{3 \times 5x^4}{2 \times 3 \times 4 \times 2^{\frac{5}{2}}\sqrt{a^7}}$$

$$+ \frac{3 \times 5 \times 7x^5}{2 \times 3 \times 4 \times 5 \times 2^{\frac{7}{2}}\sqrt{a^9}} \dots\dots$$

$$(a+x)^{\frac{1}{3}} = a^{\frac{1}{3}} + \frac{1}{3}a^{-\frac{2}{3}}x + \frac{\frac{1}{3}(-\frac{2}{3})}{1 \times 2} a^{-\frac{4}{3}}x^2 + \frac{\frac{1}{3}(-\frac{2}{3})(-\frac{4}{3})}{1 \times 2 \times 3} a^{-\frac{5}{3}}x^3$$

$$+ \frac{\frac{1}{3}(-\frac{2}{3})(-\frac{4}{3})(-\frac{8}{3})}{1 \times 2 \times 3 \times 4} a^{-\frac{7}{3}}x^4 \dots\dots$$

$$= a^{\frac{1}{3}} + \frac{x}{3\sqrt[3]{a}} - \frac{2x^2}{2 \times 3^{\frac{2}{3}}\sqrt[3]{a^5}} + \frac{2 \times 5x^3}{2 \times 3 \times 3^{\frac{4}{3}}\sqrt[3]{a^7}} - \frac{2 \times 5 \times 8x^4}{2 \times 3 \times 4 \times 3^{\frac{5}{3}}\sqrt[3]{a^9}}$$

$$+ \frac{2 \times 5 \times 8 \times 11x^5}{2 \times 3 \times 4 \times 5 \times 3^{\frac{7}{3}}\sqrt[3]{a^{11}}} \dots\dots$$

Division and Roots.

$$x^2 + x^2 = \frac{x^2}{x^2} = x^2 x^{-2} = x^0 = 1. \quad x^3 + x^3 = x^3 x^{-3} = x^0 = 1.$$

$$a^2 b^3 + ab = (a^{2-1})(b^{3-1}) = ab^2. \quad \frac{a}{x} + \frac{c}{n} = \frac{a}{x} \times \frac{n}{c} = \frac{an}{cx}.$$

Division:

$$\begin{array}{r} (x+3)x^2 + 5x + 6(x+2) \\ \underline{x^2 + 3x} \\ 2x + 6 \\ \underline{2x + 6} \\ 0 \end{array} \quad \frac{\sqrt{3}}{\sqrt{5}} = \sqrt{\frac{3}{5}} = \sqrt{\frac{15}{25}} = \frac{\sqrt{15}}{\sqrt{25}} = \frac{\sqrt{15}}{\pm 5} = \pm \frac{1}{5}\sqrt{15}$$

$$\frac{ax^2 \sqrt{cy}}{ax \sqrt{c}} = x \sqrt{y}. \quad \frac{10\sqrt{8}}{3\sqrt{5}} = \frac{\sqrt{80}}{3\sqrt{5}} = \frac{1}{3}\sqrt{16} = \frac{\pm 4}{3} = \pm 1\frac{1}{3}$$

Square Root by Binomial formula:

Example: Find the square root of 5?

Solution: In $(a+x)^{\frac{1}{2}}$ let $a=4$ and $x=1$; thence by expansion (see page 101)

$$\begin{aligned} (a+x)^{\frac{1}{2}} &= a^{\frac{1}{2}} + \frac{x}{2\sqrt{a}} - \frac{x^2}{8\sqrt{a^3}} + \frac{x^3}{16\sqrt{a^5}} - \frac{5x^4}{128\sqrt{a^7}} + \frac{7x^5}{256\sqrt{a^9}} \dots \\ &= 2 + \frac{1}{2 \times 2} - \frac{1}{8 \times 8} + \frac{1}{16 \times 32} - \frac{5}{128 \times 128} \dots \\ &= 2 + .25 - .015625 + .001953 - .000305 = 2.236 \pm. \end{aligned}$$

Cube Root by Binomial formula:

Example: Find the cube root of 9?

Solution: 8 is the cube of 2 and 1 less than 9; hence from expansion formula, page 101, there is obtained,

$$\begin{aligned} (a+x)^{\frac{1}{3}} &= (8+1)^{\frac{1}{3}} = 8^{\frac{1}{3}}(1+\frac{1}{8})^{\frac{1}{3}} = 2(1+\frac{1}{8})^{\frac{1}{3}}. \text{ But} \\ (a+x)^{\frac{1}{3}} &= a^{\frac{1}{3}} + \frac{x}{3\sqrt{a^2}} - \frac{x^2}{3^2\sqrt{a^5}} + \frac{5x^3}{3^3\sqrt{a^8}} - \frac{10x^4}{3^4\sqrt{a^{11}}} + \dots, \text{ Therefore} \\ \sqrt[3]{9} &= 2(1+\frac{1}{8})^{\frac{1}{3}} = 2 \left[1 + \frac{1}{3 \times 8} - \frac{1}{3^2 \times 8^2} + \frac{5}{3^3 \times 8^3} - \frac{10}{3^4 \times 8^4} \dots \right] \\ &= 2[1 + .0416\bar{6} - .0017361\bar{1} + .00012054 - .00001005 \dots] \\ &= 2 \times 1.04004 = 2.08008. \text{ Ans.} \end{aligned}$$

Completing the Square.—This is performed by adding a certain amount c^2 (a third term), to the first member of the (affected quadratic) equation to make it a perfect square, and the same amount to the second member so as to preserve the equality.

Example 1: Find the value of x in the equation $x^2 + 4x = 21$?

Solution: By adding c^2 to both members we have $x^2 + 4x + c^2 = c^2 + 21$, in which the first member is a perfect square, the middle term, $4x$, being equal* to $2\sqrt{x^2}\sqrt{c^2}$, whence $c^2 = 2^2 = 4$.

and $x^2 + 4x + 2^2 = 4 + 21 = 25$.

Extracting the sq. rt., $x + 2 = \pm 5$
and $x = \pm 5 - 2 = 3 \text{ or } -7. \text{ Ans.}$

Note.—Make the first term a perfect square before completing the square of the first member of the equation. This may be done by multiplying or dividing the whole equation by a constant. The first term must be positive.

* The square of a member of two terms = the square of the first + twice the product of the two + the square of the second.

Example 2: Solve $2ax^2 + 5bx = 30$? Here,

Mult. by 2, div. by a and add c^2 : $4x^2 + \frac{10b}{a}x + c^2 = c^2 + \frac{60}{a}$

Extracting the sq. rt., $2x + c = \sqrt{c^2 + \frac{60}{a}}$, in which

$$\frac{10bx}{a} = 2(2x \times c), \text{ or } c = \frac{5b}{2a}; \quad \therefore 2x = \pm \sqrt{\frac{25b^2}{4a^2} + \frac{60}{a}} - \frac{5b}{2a}$$

$$\therefore x = \pm \frac{1}{2} \sqrt{\frac{25b^2}{4a^2} + \frac{60}{a}} - \frac{5b}{4a}. \text{ Ans.}$$

Remarks on apparent fallacy of the above. To prove that $4 = 5$?

$$\text{Let } 16 - 36 = 25 - 45$$

and to complete the square, let $c^2 = \frac{81}{4}$; then

$$16 - 36 + \frac{81}{4} = 25 - 45 + \frac{81}{4}.$$

Extracting the sq. rt., $4 - \frac{9}{2} = 5 - \frac{9}{2}$. But, $\pm(4 - \frac{9}{2}) = \mp(5 - \frac{9}{2})$,
whence, apparently, $4 = 5$ (or $-\frac{1}{2} = +\frac{1}{2}$). whence, really, $4 - 4\frac{1}{2} = -5 + 4\frac{1}{2}$.

In a somewhat similar way it may also be "shown" that $2 = 1$, $1 = 0$, etc.; but the discrepancies are always apparent upon inspection.

Simultaneous Equations.—To solve any problem, the number of equations must be equal to the number of unknown quantities. This can be understood quite readily by considering that each equation is really the equation of a curve of some kind. Thus, in Fig. 1, let curve A be represented by the equation $y = mx + c$, and curve B by the equation $y^2 = 4ax$. The equations of these curves are simultaneous equations when the curves intersect at any point, as p , with common coordinates x_0 and y_0 ; and the problem is solved by determining the values of these coordinates. Thus, by substitution, $y_0^2 = (mx + c)^2 = 4ax$;

Fig. 1.

and $x_0 = \frac{y - c}{m} = \frac{y^2}{4a}$; from which we have only to solve the equation $(mx + c)^2 = 4ax$, or the equation $\frac{y - c}{m} = \frac{y^2}{4a}$, each one containing only one unknown quantity, x or y .

Simultaneous equations may be solved by three methods of eliminating all but one unknown quantity:

- (1) Elimination by substitution, as above.
- (2) Elimination by addition or subtraction, and by substitution.

Example: $3x + 4y = 18$. Mult. by 2: $6x + 8y = 36$
 $2x + 3y = 13$. Mult. by 3: $6x + 9y = 39$
 Whence by subtraction, $y = 3$

And, by substituting this value in the first equation,
 $3x + 4 \times 3 = 18$; $x = 2$.

- (3) Elimination by comparison.

Example: $3x + 4y = 18$. $x = \frac{18 - 4y}{3} = \frac{13 - 3y}{2}$; $\therefore y = 3, x = 2$.

If more than two equations are given, eliminate one unknown quantity by combining two of the equations, and proceed until one equation, with one unknown quantity, remains. Then solve for that unknown quantity and substitute its value in one of the equations to obtain the value of another unknown quantity. Proceed in this manner, substituting the values thus obtained in another equation; and so on.

For Cubic Equations, see Plane Trigonometry.

6.—LOGARITHMS OF NUMBERS.

Logarithms are useful in finding the product, quotient, powers and roots of numbers. A system of logarithms may be founded on any base, as a . If the base a raised to the m^{th} power = M , then m is the logarithm of M to the base a ; and conversely, M is the *anti-logarithm* (that is, the number corresponding to the logarithm) of m , to the same base. Thus,

Let $M = a$ number; m its log to base a . Then $\log_a M = m$; or $a^m = M$.
 Let $N = a$ number; n its log to base a . Then $\log_a N = n$; or $a^n = N$.

The following formulas and methods illustrate the use of logarithms in the process above mentioned:—

To:	Formula:	Process: find anti-logarithm of
Multiply M by N .	$MN = a^m a^n = a^{m+n}$	(Log of M) + (log of N)
Divide M by N .	$\frac{M}{N} = \frac{a^m}{a^n} = a^{m-n}$	(Log of M) - (log of N)
Raise M to the N^{th} power.	$M^N = (a^m)^N = a^{mN}$	(Log of M) $\times N$.
Extract the N^{th} root of M .	$\sqrt[N]{M} = \sqrt[N]{a^m} = a^{\frac{m}{N}}$	(Log of M) $\div N$.

Two systems of logarithms are in use, namely:

Common or Briggs System. (Founded by Briggs.) In general use for all practical purposes.	Hyperbolic, Natural or Napierian System. (Founded by Napier.) Used in pure mathematical discussion and in steam engineering.
Base $a = 10$. $a^N = N \therefore \log N = n$.	Base $e = 2.7182818 \dots$ Derivation of e :
$10^0 = 1 \therefore \log 1 = 0$.	$e = \left(1 + \frac{1}{x}\right)^x$ as x approaches infinity.
$10^1 = 10 \therefore \log 10 = 1$.	$= 1 + 1 + \frac{1}{1 \cdot 2} + \frac{1}{1 \cdot 2 \cdot 3} + \frac{1}{1 \cdot 2 \cdot 3 \cdot 4} + \dots$
$10^2 = 100 \therefore \log 100 = 2$.	$= 1 + 1 + \frac{1}{2} + \frac{1}{24} + \frac{1}{720} + \dots$
$10^{2.48} = 302 \therefore \log 302 = 2.48 +$	$= 2.7182818 \dots$

The naperian log. of a number = its common log. $\times 2.3025851 \dots$
 The common log. of a number = its hyperbolic log. $\times 0.4342945 \dots$
 Common log. of 2.3025851 = 0.3622157; of 0.4342945 = 9.6377843 - 10.

Note from the above that—

The naperian log. of the naperian base ($e = 2.7182818 \dots$) = unity.
 The common log. of the naperian base, 2.7182818 $\dots = 0.4342945$.
 The common log. of the common base ($a = 10$) = unity.
 The naperian log. of the common base, 10, = 2.3025851.

Common or Briggs System.—The logarithm of a number is composed of the *characteristic*, or integral portion to the left of the decimal point, and the *mantissa* or decimal fraction. The mantissa is all that appears in any table of logarithms and the degree of accuracy is dependent on the number of decimal places used in the mantissa. Vega's tables, to seven decimal places, are recommended for general office use in city surveying, and where the results, in general, are required accurately to the sixth or seventh significant figure.

To multiply one number by another. (Add the logs.)

Example.—Multiply 23.142 by 85.7?

$$\begin{array}{rcl} \text{Solution.—} & \log 23.142 & = 1.36436 \\ & & \overset{4}{} = \text{P. P. for 2.} \\ & \log 85.7 & = 1.93298 \\ \therefore \text{Antilog} = \text{product} = & 1983.3 & \overset{3.29738}{} \\ & \text{Ans.} & \overset{32}{} \\ & & \overset{6}{} = \text{P. P.} = 8 - \end{array}$$

To divide one number by another. (Subtract the logs.)

Example.—Divide 846.94 by 36.42?

$$\begin{array}{rcl} \text{Solution.—} & \log 846.94 & = 2.92785 \\ & \log 36.42 & = 1.56134 \\ \therefore \text{Antilog} = \text{quotient} = & 23.255 & \overset{1.36651}{} \\ & \text{Ans.} & \overset{42}{} \\ & & \overset{9}{} = \text{P. P.} = 5 - \end{array}$$

To raise a number to any power. (Multiply the log by the index of the power.)

Example.— $25.3^3 = ?$

$$\begin{array}{rcl} \text{Solution.—} & \log 25.3 & = 1.40312 \\ & \text{Multiply by 3 :} & \overset{8}{} \\ \therefore \text{Antilog} = 3\text{rd power} = & 1619.4 & \overset{4.20936}{} \\ & \text{Ans.} & \overset{25}{} \\ & & \overset{11}{} \text{ P. P.} = 4 \end{array}$$

To extract the root of a number. (Divide the log by the index of the root.)

Example 1. $\sqrt[5]{286.12} = ?$

$$\begin{array}{rcl} \text{Solution.—} & \log 286.12 & = 2.45655 \\ & \text{Divide by 5 :} & \overset{8}{} \\ \therefore \text{Antilog} = 5\text{th root} = & 3.1096 & \overset{0.49131}{} \\ & \text{Ans.} & \overset{122}{} \\ & & \overset{9}{} \text{ P. P.} = 6 \end{array}$$

Example 2.—Find the square root of the fifth power of 23.2?

Solution.—The square root of the fifth power of $N = N^{\frac{5}{2}}$, therefore multiply the log of 23.2 by $2\frac{1}{2}$ or, better, divide by .4.

$$\begin{array}{rcl} & \log 23.2 & = 1.36549 \\ & \text{Divide by .4 :} & \overset{8}{} \\ \therefore \text{Antilog} = \sqrt{23.2^5} = & 2592.5 & \overset{3.41372}{} \\ & \text{Ans.} & \overset{63}{} \\ & & \overset{9}{} \text{ P. P.} = 5 + \end{array}$$

Example 3.— $\sqrt{.09463} = ?$

$$\begin{array}{rcl} \text{Solution.—} & \log .09463 & = 8.97603 - 10. \\ & \text{Dividing by 2} & = 4.48801.5 - 5. \\ & & \overset{5}{} \\ \therefore \text{Antilog} = \text{square root} = & .30762 & \overset{9.48801.5}{} - 10 \\ & \text{Ans.} & \overset{799}{} \\ & & \overset{2.5}{} \end{array}$$

Naperian, Natural or Hyperbolic System.

A table of naperian logarithms of numbers from 1 to 10, advancing by hundredths, is given as a part of Table 1 of the common logarithms of numbers. The range of this table may be extended greatly, to include the logarithms of other numbers, as follows:

For logarithms of numbers from 1 to 10 advancing by hundredths and ten thousandths; use the "difference" column in the table. Thus, to find the log of 4.6953, add $\frac{53}{100}$ of the difference, 213, to the log of 4.69, equals $1.54543 + 113 = 1.54656$. Ans.

For logarithms of numbers from 10 to 100: Divide the number by 10, find the log of the quotient, from the table, and add 2.302585 (the log of 10). Thus, to find the log of 46.72. $\text{Log } 4.672 = 1.54116 + 43$, which, added to 2.302585 = 3.84418. Ans.

Rule.—Add 2.302585 to the log of $1/10$ of the number.

For logarithms of numbers from 100 to 1000: Divided the number by 100, find the log of the quotient, from the table, and add $2 \times 2.302585 = 4.60517$ (the log of 100).

Rule.—Add 4.60517 to the log of $1/100$ of the number.

In general, to find the naperian logarithm of any number, add $\pi \times 2.302585$ to the naperian log of $\frac{1}{\pi} \times$ the number; the factor π to be selected and some power of 10, so as to bring the new number within the range of the table, i. e., from 1 to 10.

Log of 10.	Multiple:	Log of 10.	Multiple:
2.3025851	$\times 2 = 4.6051702$	2.3025851	$\times 5 = 11.5129255$
	$\times 3 = 6.9077553$		$\times 6 = 13.8155106$
	$\times 4 = 9.2103404$		$\times 7 = 16.1180957$

To find the antilog, proceed in a manner inverse to the above method of finding the log.

Example.—Of what number is 4.85203 the log?

Solution.—The highest multiple of 2.3025851 below the given log is 4.60517, obtained by the factor 2 corresponding with the factor 100 of the number. From the table of naperian logarithms, Table 1, we find that the number corresponding to the log of the difference, 0.24686, is 1.28. But the given log, 4.85203, is of a number 100 times as large, therefore its antilog is $1.28 \times 100 = 128$. Ans.

Given by log	= 4.85203
Multiple	= 4.60517
Diff.	= 0.24686

Slide Rules—Logarithmic slide rules are instruments graduated on a logarithmic basis for performing calculations involving multiplication (including powers) and division (including roots and reciprocals) of numbers.

Fig. 1.

The principle of the slide rule is very simple, although some of the instruments themselves are complex and expensive.

The plain slide rule, Fig. 1, is usually from ten to eighteen inches long. (The longer the scale, the more accurate.) It consists of the upper and lower "fixed" scales *A* and *B*, graduated on one piece and grooved to receive the sliding piece, on which are graduated the scales *a* and *b*. Note that scales *A* and *a* are similar, as are also *B* and *b*; but that the former are in double series (from 1 to 10) while the latter are in single series only. The advantage of this system will be explained below.

Fig. 1 shows the upper fixed and sliding scales, *A* and *a*, together with their logarithmic bases. These two scales (or the two lower ones, either) may be used in performing any simple operation in multiplication or division. For instance, as the scales *A* and *a* are now set we can find the product of any number multiplied by 2; or, inversely, the quotient of any number divided by 2. Thus, $2 \times 1 = 2$; $2 \times 2 = 4$; $2 \times 3 = 6$, etc. Likewise, $10 \div 2 = 5$; $20 \div 2 = 10$; etc. Note that the logarithm of the product = the sum of the logarithms of the factors; thus, $\log$ of 40 (= 1.6) is equal to $\log$ of 20 + $\log$ of 2 = 1.3 + 0.3. Similarly, the log of the quotient is the log dividend minus the log divisor. Of course the logarithms themselves do not appear on the slide rule, but the numbers are arranged so their logarithms form series equally spaced, and the principle remains. To multiply any number *q* by *n*: Set 1 of scale *a* opposite *q* of scale *A*, and opposite *n* of scale *a* read the product *p* on scale *A*. To divide any number *p* by *n*: Set *n* of scale *a* opposite *p* of scale *A*, and opposite 1 of scale *a* read the quotient *q* on scale *A*. To find the reciprocal of a number: Divide 1 by that number; or, invert the sliding scale, end for end, with ends of both scales, *A* and *a*, opposite, and the reciprocal of any number on one scale, as *A*, will be found directly opposite on the other scale, as *a*.

To facilitate operations, and for accuracy, each slide rule is provided with a movable index with a vertical hair line.

Fig. 2 shows the ordinary slide rule with double scale. With the movable index, the square root of any number on scale *A* will be found

Fig. 2.

directly below on scale *B*. In like manner, the square of any number on scale *B* is found opposite, on scale *A*. Furthermore, the cube of any number on scale *B* may be found by multiplying its corresponding square on scale *A* by the number itself on scale *a*, reading the cube on scale *A*. Thus, Fig. 2, the cube of 1.59 (scale *B*) is found on scale *A* opposite 1.59 of scale *a*, and is equal to 4. Clearly, then, the cube root of any number *n* (scale *A*) is found by making the reading on scale *a*, opposite *n*, equal to the reading on scale *B* opposite 1 of scale *b*, and these equal readings are the cube root of the number. Thus, the cube root of 4 = 1.59.

Thatcher's calculating instrument is a cylinder four inches in diameter and about eighteen inches long, which acts as a sliding scale inside a framework of twenty parallel bars forming the fixed scales. This instrument is by far the best on the market. It was sold formerly at \$25.00, a price barely exceeding the cost of manufacture, and is now listed at \$35.00; and with reading glass, \$45.00. Results may be obtained to four or five decimal places. It is nearly as accurate as a five-place logarithmic table.

Slide rules are used in all logarithmic and trigonometric operations, and no engineer should be without one. Books giving full directions in the use of the slide rule can be obtained for from 25 to 75 cents. They explain the method of solving such equations as:

$$y = \frac{ax}{b}; y = \frac{ax}{b^2}; y = \frac{ax^3}{b}; y = a \frac{x^2}{b^2}; y = \sqrt{\frac{ax}{b}}; y = a \sqrt{\frac{x}{b}}; \text{ etc.}$$

7.—PLANE GEOMETRY

(See also Mensuration.)

Angles and Lines.—

Straight line: $a b$. *Oblique lines:* ab, cd .
Broken line: $a o d$. *Oblique angles:* A, B .
Acute angle: A . *Adjacent angles:* A, B ; A, C .
Obtuse angle: B . *Reflex angle:* Greater than 180° and less than 360° .

Complementary angles: A and C ($A + C = 90^\circ$); each is the complement of the other.

Supplementary angles: A and B ($A + B = 180^\circ$); each is the supplement of the other.

Right angle: $a o e$ ($= 90^\circ$); $e o$ is perpendicular to $a b$.

Straight angle: $a o b$ ($= 180^\circ$); sides form two right angles.

Conjugate angles: Two angles, about e point, whose sum equals 360° .

Vertical angles: A and A ; B and B .

Triangles.—

Triangle: Plane bounded by three straight sides, Fig. 2.

Perimeter: Sum of the sides.

Angles: The interior angles (sum $= 180^\circ$).

Fig. 2.

Fig. 3.

Fig. 4.

Successive partial exterior angles: A', B' and C' (sum $= 360^\circ$).

Right triangle: One of its angles a right angle, Fig. 3.

Scalene " No two of its sides equal, Fig. 4.

Obtuse " One of its angles obtuse, Fig. 4.

Fig. 5.

Fig. 6.

Figs. 7.

Isosceles triangle: Two of its sides equal, Fig. 5.

Acute " All of its angles acute, Fig. 5.

Equilateral " All of its sides equal, Fig. 6.

Equiangular " All of its angles equal, Fig. 6.

Area of any triangle $= \frac{1}{2}$ base $\times$ altitude.

Quadrilaterals.—

Quadrilateral: Plane bounded by four straight sides, Fig. 8.

Sum of interior angles (A, B, C, D) $= 360^\circ$;

Sum of partial successive exterior angles (A', B', C', D') $= 360^\circ$;

Sum of exterior angles (complete) $= 1080^\circ$.

Square: All sides equal, and each angle 90° , Fig. 9.

Rectangle: Opposite sides parallel, and each angle 90° , Fig. 10.

Parallelogram: Opposite sides parallel, Fig. 11.

Fig. 1.

Fig. 8.

Fig. 9.

Fig. 10.

Fig. 11.

Fig. 12.

Fig. 13.

Fig. 14.

Fig. 15.

Rhomboid: Opposite sides parallel, and all angles oblique, Fig. 12.

Rhombus: All sides equal, all angles oblique, Fig. 13.

Trapezoid: Two sides, only, parallel, Fig. 14.

Trapezium: No two sides parallel, Fig. 15.

Polygons (General).—

Polygon: Plane bounded by straight sides, Fig. 16.

3 = triangle, 4 = quadrilateral, 5 = pentagon, 6 = hexagon.

7 = heptagon, 8 = octagon, 9 = nonagon, 10 = decagon,

11 = undecagon, 12 = dodecagon.

Sum of interior angles (A, B, C , etc.) = $180^\circ \times (\text{number of sides} - 2)$.

Sum of partial successive exterior angles (A', B', C' , etc.) = 360° .

Sum of exterior angles (complete) = $360^\circ + \text{number of sides} \times 180^\circ$.

Regular Polygons.—

Regular polygon: All sides equal and all angles equal, Fig. 17.

Circle: A regular polygon with an infinite number of sides.

Radius of polygon: Radius (r) of circumscribed circle.

Apothem of polygon: Radius (a) of inscribed circle.

Perimeter: Sum of the sides.

Area: $\frac{1}{2}$ apothem $\times$ perimeter.

Circle.—

Tangent: Touches circumference at one point.

Secant: Intersects circumference at two points.

Diameter: Intersects center and is limited by circumference.

Radius: Distance from center to circumference.

Chord: A secant limited by the circumference.

Arc: A portion of the circumference.

Segment: Area bounded by arc and chord.

Sector: Area bounded by two radii and the intercepted arc.

Quadrant: Sector equal to quarter of a circle.

Semicircle: Sector equal to half a circle.

Circumference = diameter $\times \pi$. $\pi = 3.1415927$.

Diameter = circumference $\times \frac{1}{\pi}$. $\frac{1}{\pi} = 0.3183099$.

Area of circle = diameter² $\times \frac{\pi}{4}$. $\frac{\pi}{4} = 0.7853982$.

Fig. 16.

Fig. 17.

Fig. 18.

Problems in Construction of Figures.—

Intercepting circles: Common chord is at right angle to line joining centers of circles, Fig. 19. Used in laying off 90° .

To lay off 90° , 45° , 60° and 30° :

Fig. 19.

Fig. 20.

Center of circle: Intersection of perpendiculars bisecting any two chords, Fig. 21.

An inscribed angle in a semicircle = 90° , Fig. 22.

An angle from a point on the circumference is measured by half the intercepted arc (angle = $\frac{1}{2}$ arc), Fig. 23.

An angle included by a tangent and adjacent chord is measured by half the intercepted arc; (angle = $\frac{1}{2}$ arc), Fig. 24.

Fig. 21.

Fig. 22.

Fig. 23.

Fig. 24.

Equal angles from a point, o , on the circumference subtend equal arcs and equal chords, Fig. 25.

Railway curve: The two preceding propositions are fundamental in the laying out of railway curves. The chord is usually 100 ft. with a

Fig. 25.

Fig. 26.

Fig. 27.

central angle D° which equals the degree of curvature. The deflection angle d° is always one-half the central angle D° ; hence for one chord, or station, the deflection angle is one-half the degree of curvature.

Circle inscribed in a triangle: Center of circle is intersection of lines bisecting the angles, Fig. 27. Radius is shortest distance to either side.

Circle circumscribing a triangle: Center of circle is intersection of perpendiculars bisecting the sides, Fig. 28.

Fig. 28.

Proportion by segments of chords: $ab=cd$; $\frac{a}{c} = \frac{d}{b}$; $\frac{a}{d} = \frac{c}{b}$. ade and cbf are similar triangles, Fig. 29.

Mean proportional: By similar triangles, $\frac{a}{c} = \frac{c}{b}$, whence c is a mean proportional between a and b ($a \cdot b = c^2$), Fig. 30.

Inscribed square and octagon; Circumscribed circle, Fig. 31.

Circumscribed square and octagon; Inscribed circle, Fig. 32.

Fig. 29.

Fig. 30.

Fig. 31.

Fig. 32.

Pentagon inscribed in a circle: bd is one side of the pentagon (5 sides). Process: Bisect radius at a ; $ac = ab$; $bd = bc$. Step off de, ef , etc., = bd , and connect, Fig. 33.

Decagon inscribed in a circle: Bisect the circular arcs of an inscribed pentagon, making twice the number of sides, Fig. 34.

Pentagon of given side ab : Erect the perpendicular $bc = \frac{1}{2}$ side ab ; produce ac to d so that $cd = cb$; then $bd = be = ae =$ radius of pentagon = radius of circumscribed circle, with center at e . Step off $a f, f g$, etc., = ab , and connect, Fig. 35.

Fig. 33.

Fig. 34.

Fig. 35.

Hexagon inscribed in a circle: Each side is equal to the radius, Fig. 36.

Equilateral Triangle: Connect alternate points of hexagon, making half the number of sides, Fig. 37.

Dodecagon: Bisect the circular arcs of an inscribed hexagon, making twice the number of sides, Fig. 38.

Fig. 36.

Fig. 37.

Fig. 38.

8.—SOLID GEOMETRY.

Planes, Angles and Lines.—

Plane: Determined by (1) two parallel lines; (2) two intersecting lines; (3) three points not in the same straight line; (4) a straight line and a point outside of it.

Straight line: Intersection of two planes not parallel, as ab , Fig. 1.

Dihedral angle: The angle between two planes, measured at right angle to each plane and to the line of their intersection, or edge, as A , Fig. 1.

Right dihedral angle: A dihedral angle that is 90° , Fig. 2.

Fig. 1.

Fig. 2.

Other angles: Acute, obtuse, complementary, supplementary, adjacent, etc., as in Plane Geometry.

Coordinate planes: V and H , Fig. 3, are planes perpendicular to each other; hence, any line v in one plane, if perpendicular to ab , is perpendicular also to the other plane.

Fig. 3.

Polyhedrons.—

Polyhedron: Solid bounded by planes.

Tetrahedron: 4 triangular faces; 6 edges, Fig. 4.

Hexahedron: 6 square faces; 12 edges, Fig. 5.

Fig. 4.

Fig. 5.

Fig. 6.

Fig. 7.

Fig. 8.

Octahedron: 8 triangular faces; 12 edges, Fig. 6.

Dodecahedron: 12 pentagonal faces; 30 edges, Fig. 7.

Icosahedron: 20 triangular faces; 30 edges, Fig. 8.

Prisms.—

Prism: A polyhedron with two opposite faces parallel and equal polygons the other faces parallelograms, Fig. 9.

Right prism: Lateral edges perpendicular to bases, Fig. 10.

Regular prism: A right prism whose bases are regular polygons.

Oblique prism: Lateral edges are oblique to bases, Fig. 11.

Triangular prism: Bases are triangles, Fig. 11.

Fig. 9.

Fig. 10.

Fig. 11.

Quadrangular prism: Bases are quadrilaterals, Fig. 12.

Parallelepiped: Prism whose bases are parallelograms.

Right parallelepiped: Lateral edges are perpendicular to the bases, Fig. 12.

Rectangular parallelepiped: Six faces are rectangles, Fig. 12.

Cube: Parallelepiped whose six faces are squares, Fig. 13.

Volume of any prism = area of base $\times$ altitude.

Truncated prism: Portion included between base and plane section oblique to base, Fig. 14.

Fig. 12.

Fig. 13.

Fig. 14.

Pyramids.—

Pyramid: Polyhedron whose base is a polygon and whose sides are triangles joining a common apex or top, Fig. 15.

Altitude: Perpendicular distance from apex to plane of base.

Triangular pyramid: Base is a triangle ($\therefore$ solid is a tetrahedron).

Quadrangular pyramid: Base is a quadrilateral.

Regular pyramid: Base is a polygon, and apex is directly over its center, Fig. 16.

Fig. 15.

Fig. 16.

Fig. 17.

Fig. 18.

Irregular pyramid: One that is not regular.

Volume of any pyramid: $\frac{1}{3}$ area of base $\times$ altitude.

Slant height: Distance along any lateral face from its apex to the middle of its base.

Truncated pyramid: That portion between the base and a plane section cutting all the sides, Fig. 17.

Frustum of a pyramid: That portion between the base and a plane section parallel with the base, Fig. 18.

Cylinders.—

Cylinder = circular cylinder: Two bases are circular and parallel; all sections parallel with the bases are circular, Fig. 19.

Elliptic cylinder: Two bases are elliptical and parallel; all sections parallel with the bases are elliptical.

Fig. 19.

Right cylinder: Elements are perpendicular to the bases.

Oblique cylinder: Elements are oblique to the bases.

Volume of any cylinder = area of base $\times$ altitude.

Cones.—

Cone = circular cone: Base and all sections parallel with it are circular; elements composing the sides meet at a common apex or top, Fig. 20.

Elliptic cone: Base and all sections parallel with it are elliptical.

Altitude: Perpendicular distance from apex to plane of base.

Right cone: Cone with axis perpendicular to base.

Oblique cone: Cone with axis oblique to base.

Fig. 20.

Fig. 21.

Fig. 22.

Volume of any cone: $\frac{1}{3}$ area of base $\times$ altitude.

Truncated cone: That portion between the base and a plane cutting all the elements, Fig. 21.

Frustum of a cone: That portion between the base and a plane section parallel with the base, Fig. 22.

Spheres.—

Sphere: Solid whose every section is circular, Fig. 23.

Radius: Distance from center to surface.

Diameter: Two radii forming one straight line.

Great circle: The largest plane section (cuts center of sphere).

Pole of a circle: End of diameter or axis perpendicular to the plane of the circle.

Fig. 23.

Fig. 24.

Fig. 25.

Fig. 26.

Fig. 27.

Arc of a great circle: Shortest surface distance between two points on surface of sphere.

Polar distance of a circle: Distance from nearest pole to circumference of circle.

Quadrant: Polar distance of a great circle.

Surface of sphere = $4 \pi \text{ radius}^2$.

Volume of sphere = $\frac{4}{3} \pi \text{ radius}^3$.

Zone: Portion of surface between two parallel planes, Fig. 24.

Lune: Portion of surface between two semi-circumferences of great circles, Fig. 25.

Spherical segment: Portion of sphere between two parallel planes, Fig. 26.

Spherical pyramid: Apex corresponds to center of sphere, sides are radial planes, and base is a spherical polygon Fig. 27.

Spherical cone: Cone with spherical base, Fig. 27.

9.—PLANE TRIGONOMETRY.

Plane Trigonometry deals with the functions of plane triangles, and shows how to compute the unknown elements when certain of the known elements are given. The six elements of a triangle are its three sides and three angles; and three of these, one of which must be a side, must be known in order to solve the triangle.

Trigonometric functions are the ratios of the sides of a right angle triangle. There are six primary ratios, namely, *sine*, *cosine*, *tangent*, *cotangent*, *secant* and *cosecant*. In addition to these, however, there are two secondary functions sometimes employed, namely, *versed sine* and *coverSED sine*; and two tertiary functions seldom used, namely, *exsecant* and *coexsecant*.

The following trigonometric functions or ratios refer to Fig. 1, in which —

h = hypothenuse,
 p = perpendicular,
 b = base,
 A = angle at base,
 B = angle opposite base.
 sine A = cosine B , etc.

Fig. 1.

PRIMARY FUNCTIONS:

$$\sin A (= \cos B) = \frac{p}{h}.$$

$$\cos A (= \sin B) = \frac{b}{h}.$$

$$\tan A (= \cot B) = \frac{p}{b}.$$

$$\cot A (= \tan B) = \frac{b}{p}.$$

$$\sec A (= \csc B) = \frac{h}{b}.$$

$$\csc A (= \sec B) = \frac{h}{p}.$$

SECONDARY FUNCTIONS:

$$\text{vrs } A (= \text{cvs } B) = 1 - \cos A = 1 - \frac{b}{h} = \frac{h-b}{h}.$$

$$\text{cvs } A (= \text{vrs } B) = 1 - \sin A = 1 - \frac{p}{h} = \frac{h-p}{h}.$$

TERTIARY FUNCTIONS:

$$\text{xsc } A (= \text{cxc } B) = \sec A - 1 = \frac{h}{b} - 1 = \frac{h-b}{b}.$$

$$\text{cxc } A (= \text{xsc } B) = \csc A - 1 = \frac{h}{p} - 1 = \frac{h-p}{p}.$$

1.—EQUIVALENT VALUES OF PRIMARY FUNCTIONS OF ANY ANGLE x IN PURE TERMS OF EACH OF THE OTHER FUNCTIONS.

$\sin$	$\cos$	$\tan$	$\cot$	$\sec$	$\csc$
$\sin x$	$= \sqrt{1 - \cos^2 x}$	$= \frac{\tan x}{\sqrt{1 + \tan^2 x}}$	$= \frac{1}{\sqrt{1 + \cot^2 x}}$	$= \frac{\sqrt{\sec^2 x - 1}}{\sec x}$	$= \frac{1}{\csc x}$
$\sqrt{1 - \sin^2 x}$	$= \cos x$	$= \frac{1}{\sqrt{1 + \tan^2 x}}$	$= \frac{\cot x}{\sqrt{1 + \cot^2 x}}$	$= \frac{1}{\sec x}$	$= \frac{\sqrt{\csc^2 x - 1}}{\csc x}$
$\frac{\sin x}{\sqrt{1 - \sin^2 x}}$	$= \frac{\sqrt{1 - \cos^2 x}}{\cos x}$	$= \tan x$	$= \frac{1}{\cot x}$	$= \frac{\sqrt{\sec^2 x - 1}}{\sec x}$	$= \frac{1}{\sqrt{\csc^2 x - 1}}$
$\frac{\sqrt{1 - \sin^2 x}}{\sin x}$	$= \frac{\cos x}{\sqrt{1 - \cos^2 x}}$	$= \frac{1}{\tan x}$	$= \cot x$	$= \frac{1}{\sqrt{\sec^2 x - 1}}$	$= \frac{\sqrt{\csc^2 x - 1}}{\csc x}$
$\frac{1}{\sqrt{1 - \sin^2 x}}$	$= \frac{1}{\cos x}$	$= \sqrt{1 + \tan^2 x}$	$= \frac{\sqrt{1 + \cot^2 x}}{\cot x}$	$= \sec x$	$= \frac{\csc x}{\sqrt{\csc^2 x - 1}}$
$\frac{1}{\sin x}$	$= \frac{1}{\sqrt{1 - \cos^2 x}}$	$= \frac{\sqrt{1 + \tan^2 x}}{\tan x}$	$= \sqrt{1 + \cot^2 x}$	$= \frac{\sec x}{\sqrt{\sec^2 x - 1}}$	$= \csc x$

OTHER EQUIVALENT VALUES OF PRIMARY FUNCTIONS OF ANY ANGLE x AND (ANGLE x)².

$\sin x = \frac{\cos x}{\cot x} = \cos x \tan x.$	$\sin^2 x = 1 - \cos^2 x.$	$\frac{1}{\sin^2 x} = 1 + \frac{\cos^2 x}{\sin^2 x}$
$\cos x = \frac{\sin x}{\tan x} = \sin x \cot x.$	$\cos^2 x = 1 - \sin^2 x.$	$\frac{1}{\cos^2 x} = 1 + \frac{\sin^2 x}{\cos^2 x}$
$\tan x = \frac{\sin x}{\cos x} = \sin x \sec x.$	$\tan^2 x = \sec^2 x - 1.$	$\frac{1}{\tan^2 x} = \frac{\cos^2 x}{\sin^2 x}$
$\cot x = \frac{\cos x}{\sin x} = \cos x \csc x.$	$\cot^2 x = \csc^2 x - 1.$	$\frac{1}{\cot^2 x} = \frac{\sin^2 x}{\cos^2 x}$
$\sec x = \frac{\tan x}{\sin x} = \tan x \csc x.$	$\sec^2 x = 1 + \tan^2 x.$	$\frac{1}{\sec^2 x} = \frac{\sin^2 x}{\tan^2 x}$
$\csc x = \frac{\cot x}{\cos x} = \cot x \sec x.$	$\csc^2 x = 1 + \cot^2 x.$	$\frac{1}{\csc^2 x} = \frac{\cos^2 x}{\cot^2 x}$

Values of Trigonometric functions in the four quadrants.—In Fig. 2 the angle x_1 lies wholly within the first quadrant, 0° to 90° ; x_2 extends into the second quadrant, comprising angles from 90° to 180° ; x_3 extends into the third quadrant, comprising angles from 180° to 270° ; and x_4 extends into the fourth quadrant, comprising angles from 270° to 360° .

It will be noticed that in all cases the sine falls perpendicularly upon the axis $X-X$ and that the cosine falls perpendicularly upon the coordinate axis $Y-Y$. Assuming arbitrarily that, when the sine is *above* the axis of $X-X$, it is *plus* and when *below*, it is *minus*; also, that when the cosine is to the *right* of the axis $Y-Y$ it is *plus*, and when to the *left* it is *minus*; we obtain the following sign values of the fundamental sign functions:

	1st quad.	2nd quad.	3rd quad.	4th quad.
Sine.....	+	+	-	-
Cosine.....	+	-	-	+

The sign values may further be extended to the other trigonometric functions by remembering that

$$\tan x = \frac{\sin x}{\cos x}, \cot x = \frac{\cos x}{\sin x}, \sec x = \frac{1}{\cos x}, \csc x = \frac{1}{\sin x},$$

$$\text{vrs } x = 1 - \cos x, \text{cvs } x = 1 - \sin x, \text{xsc } x = \sec x - 1, \text{cxc } x = \csc x - 1;$$

and that in either multiplication or division, like signs give plus and unlike, minus. Hence the following table:

	1st quad.	2nd quad.	3rd quad.	4th quad.
Sine, cosecant, coexsecant...	+	+	-	-
Cosine, secant, exsecant....	+	-	-	+
Tangent, cotangent.....	+	-	+	-
Versed sine, covered sine..	+	+	+	+

Fig. 2.

2.—NATURAL FUNCTIONS OF ANGLES FROM 0° TO 360°.

Angle	Sin	Cos	Tan	Cot	Sec	Csc	Vrs	Cvs	Xsc	Cxc

Functions of complement, supplement, etc., of any angle x .

The complement of any angle x is $90^\circ - x$. Thus, in Fig. 1, page 136, B is the complement of A .

The supplement of any angle x is $180^\circ - x$, etc.

In the following Table, the first four primary functions of angles extending into either of the four quadrants (see Fig. 2, page 137) are reduced to the functions of angles not greater than 90° .

	1st Quadrant.	2nd Quadrant.
$\sin x$	$\sin x_1 = \cos (90^\circ - x_1)$	$\left\{ \begin{array}{l} \sin x_2 = \sin (180^\circ - x_2) \\ \sin x_2 = \cos (x_2 - 90^\circ) \end{array} \right\}$
$\cos x$	$\cos x_1 = \sin (90^\circ - x_1)$	$\left\{ \begin{array}{l} \cos x_2 = -\cos (180^\circ - x_2) \\ \cos x_2 = -\sin (x_2 - 90^\circ) \end{array} \right\}$
$\tan x$	$\tan x_1 = \cot (90^\circ - x_1)$	$\left\{ \begin{array}{l} \tan x_2 = -\tan (180^\circ - x_2) \\ \tan x_2 = -\cot (x_2 - 90^\circ) \end{array} \right\}$
$\cot x$	$\cot x_1 = \tan (90^\circ - x_1)$	$\left\{ \begin{array}{l} \cot x_2 = -\cot (180^\circ - x_2) \\ \cot x_2 = -\tan (x_2 - 90^\circ) \end{array} \right\}$
	3rd Quadrant.	4th Quadrant.
$\sin x$	$\left\{ \begin{array}{l} \sin x_3 = -\sin (x_3 - 180^\circ) \\ \sin x_3 = -\cos (270^\circ - x_3) \end{array} \right\}$	$\left\{ \begin{array}{l} \sin x_4 = -\sin (360^\circ - x_4) \\ \sin x_4 = -\cos (x_4 - 270^\circ) \end{array} \right\}$
$\cos x$	$\left\{ \begin{array}{l} \cos x_3 = -\cos (x_3 - 180^\circ) \\ \cos x_3 = -\sin (270^\circ - x_3) \end{array} \right\}$	$\left\{ \begin{array}{l} \cos x_4 = \cos (360^\circ - x_4) \\ \cos x_4 = \sin (x_4 - 270^\circ) \end{array} \right\}$
$\tan x$	$\left\{ \begin{array}{l} \tan x_3 = \tan (x_3 - 180^\circ) \\ \tan x_3 = \cot (270^\circ - x_3) \end{array} \right\}$	$\left\{ \begin{array}{l} \tan x_4 = -\tan (360^\circ - x_4) \\ \tan x_4 = -\cot (x_4 - 270^\circ) \end{array} \right\}$
$\cot x$	$\left\{ \begin{array}{l} \cot x_3 = \cot (x_3 - 180^\circ) \\ \cot x_3 = \tan (270^\circ - x_3) \end{array} \right\}$	$\left\{ \begin{array}{l} \cot x_4 = -\cot (360^\circ - x_4) \\ \cot x_4 = -\tan (x_4 - 270^\circ) \end{array} \right\}$

Functions of the sum of two angles $(x+y)$.

$$\sin (x+y) = \sin x \cos y + \cos x \sin y.$$

$$\cos (x+y) = \cos x \cos y - \sin x \sin y.$$

$$\tan (x+y) = \frac{\tan x + \tan y}{1 - \tan x \tan y}.$$

$$\cot (x+y) = \frac{\cot x \cot y - 1}{\cot y + \cot x}.$$

$$\sin x + \sin y = 2 \sin \frac{1}{2} (x+y) \cos \frac{1}{2} (x-y).$$

$$\cos x + \cos y = 2 \cos \frac{1}{2} (x+y) \cos \frac{1}{2} (x-y).$$

Functions of the difference of two angles $(x-y)$.

$$\sin (x-y) = \sin x \cos y - \cos x \sin y.$$

$$\cos (x-y) = \cos x \cos y + \sin x \sin y.$$

$$\tan (x-y) = \frac{\tan x - \tan y}{1 + \tan x \tan y}.$$

$$\cot (x-y) = \frac{\cot x \cot y + 1}{\cot y - \cot x}.$$

$$\sin x - \sin y = 2 \cos \frac{1}{2} (x+y) \sin \frac{1}{2} (x-y).$$

$$\cos x - \cos y = -2 \sin \frac{1}{2} (x+y) \sin \frac{1}{2} (x-y).$$

Functions of half an angle ($\frac{1}{2}x$).

$$\sin \frac{1}{2}x = \frac{\sin x}{2 \cos \frac{1}{2}x} = \sqrt{\frac{\text{vers } x}{2}} = \sqrt{\frac{1 - \cos x}{2}}.$$

$$\cos \frac{1}{2}x = \frac{\sin x}{2 \sin \frac{1}{2}x} = \sqrt{\frac{1 + \cos x}{2}}.$$

$$\tan \frac{1}{2}x = \frac{1 - \cos x}{\sin x} = \frac{\sin x}{1 + \cos x} = \text{cosec } x - \cot x = \sqrt{\frac{1 - \cos x}{1 + \cos x}}.$$

$$\cot \frac{1}{2}x = \frac{1 + \cos x}{\sin x} = \frac{\sin x}{1 - \cos x} = \frac{\sin x}{\text{vers } x} = \frac{1}{\text{cosec } x - \cot x}.$$

Functions of twice an angle ($2x$).

$$\sin 2x = 2 \sin x \cos x = \frac{2 \tan x}{1 + \tan^2 x}.$$

$$\cos 2x = \cos^2 x - \sin^2 x = 1 - 2 \sin^2 x = 2 \cos^2 x - 1 = \frac{1 - \tan^2 x}{1 + \tan^2 x}.$$

$$\tan 2x = \frac{2 \tan x}{1 - \tan^2 x} = \frac{\sin 3x - \sin x}{\cos 3x + \cos x}.$$

$$\cot 2x = \frac{\cot^2 x - 1}{2 \cot x}.$$

Functions of three times an angle ($3x$).

$$\sin 3x = 3 \sin x - 4 \sin^3 x.$$

$$\cos 3x = 4 \cos^3 x - 3 \cos x.$$

$$\tan 3x = \frac{3 \tan x - \tan^3 x}{1 - 3 \tan^2 x}.$$

Functions of four times an angle ($4x$).

$$\sin 4x = 4 \sin x \cos x - 8 \sin^3 x \cos x.$$

$$\cos 4x = 1 - 8 \cos^2 x + 8 \cos^4 x.$$

$$\tan 4x = \frac{4 \tan x - 4 \tan^3 x}{1 - 6 \tan^2 x + \tan^4 x}.$$

Inverse Trigonometric Functions.—In logarithms we have seen that the anti-logarithm N is a number whose logarithm is n ; that is, it is the number corresponding to the logarithm n . Similarly, in Trigonometry, we have—

The anti-sine of s = angle whose sine is s = angle corresponding to sine s .

Thus, $\sin A = s$, or $A = \sin^{-1}s$ (Reads A = anti-sine or inverse sine of s).

The anti-cosine of c = angle whose cosine is c = angle corresponding to cosine c .

Thus, $\cos A = c$, or $A = \cos^{-1}c$ (Reads A = anti-cosine or inverse cosine of c).

And so on with the remaining functions.

This must not be confused with the negative exponent, -1 , as $x^{-1} = \frac{1}{x}$;
 $x^{-1} = \frac{1}{x}$; $(\sin x)^{-1} = \frac{1}{\sin x}$; $(\cos y)^{-1} = \frac{1}{\cos y}$; etc. But $\sin A = \sin (\sin^{-1}s) = s$;

$\cos A = \cos (\cos^{-1}c) = c$; etc.

Examples: $\frac{1}{2} = \sin 30^\circ \therefore$ the anti-sine of $\frac{1}{2}$ is 30° .

$\frac{\sqrt{2}}{2} = \cos 45^\circ \therefore$ the anti-cosine of $\frac{\sqrt{2}}{2}$ is 45° .

$\sqrt{3} = \tan 60^\circ \therefore$ the anti-tangent of $\sqrt{3}$ is 60° .

Natural and logarithmic trigonometric functions.—On pages 144 to 175 will be found tables (3 and 4) of natural functions, and on pages 176 to 198 a table (5) of logarithmic functions, of angles up to 90° or in the first quadrant. For angles greater than 90° see Table 1 of functions of any angle reduced to function of an angle not greater than 90° . In general, the following rules are convenient to memorize:

Sine of an angle = the cosine of its complement.
 " " " = " sine " supplement.
 Tangent " " = " cotangent " complement.
 " " " = " -tangent " supplement.

In using the natural functions the processes of multiplication and division have to be performed, while the logarithmic functions are designed to reduce these to the simple processes of addition and subtraction. Logarithmic functions are simply logarithms of the natural functions.

The tables are as follows:

Table 3, page 144, Natural Sines, Tangents, Cotangents, Cosines, (Versed Sines, Covered Sines).

Table 4, page 167, Natural Secants, Cosecants, (Exsecants, Coexsecants).

Table 5, page 175, Logarithmic Sines, Tangents, Cotangents, Cosines (Secants, Cosecants).

Solution of right angle triangles.—The six primary functions are all that need be employed in the solution of any triangle:

$$(1) \sin A (-\cos B) = \frac{p}{h}, \text{ Whence, } p = h \sin A = h \cos B.$$

$$(2) \cos A (-\sin B) = \frac{b}{h}, \quad " \quad b = h \cos A = h \sin B.$$

$$(3) \tan A (-\cot B) = \frac{p}{b}, \quad " \quad p = b \tan A = b \cot B.$$

$$(4) \cot A (-\tan B) = \frac{b}{p}, \quad " \quad b = p \cot A = p \tan B.$$

$$(5) \sec A (-\csc B) = \frac{h}{b}, \quad " \quad h = b \sec A = b \csc B; \text{ or } h = \frac{b}{\cos A} = \frac{b}{\sin B}$$

$$(6) \csc A (-\sec B) = \frac{h}{p}, \quad " \quad h = p \csc A = p \sec B; \text{ or } h = \frac{p}{\sin A} = \frac{p}{\cos B}$$

$$[\text{Also } h^2 = b^2 + p^2. \text{ Whence } h = \sqrt{b^2 + p^2}; b = \sqrt{h^2 - p^2}; p = \sqrt{h^2 - b^2}.]$$

Example 1.

Given: $A = 32^\circ, h = 20.3$.

Required: p .

Solution: (1) $p = h \sin A$.

By natural functions.

$$\sin A = \sin 32^\circ = .52992$$

$$p = .52992 \times 20.3 = 10.757. \text{ Ans.}$$

By logarithmic functions.

$$\log 20.3 = 1.30750$$

$$\log \sin 32^\circ = 9.72421$$

$$\text{Ans. } 10.757. \quad \bar{1}.03171$$

Example 2.

Given: $p = 25, b = 20$.

Required: Angle B .

Solution: (4) $\tan B = \frac{b}{p}$.

By natural functions.

$$\tan B = \frac{b}{p} = \frac{20}{25} = .8.$$

$$\text{Angle } B = \tan^{-1}.8 = 38^\circ - 40'. \text{ Ans.}$$

By logarithmic functions.

$$\log 20 = 1.30103$$

$$\log 25 = 1.39794$$

$$\text{Ans. } 38^\circ - 40' \quad \bar{9}.90309$$

Fig. 3.

*Example 3.*Given: $A = 16^\circ - 10'$, $p = 40$.Required: h .Solution: (6) $h = p + \sin A$.*By natural functions.*

$$\sin A = \sin 16^\circ - 10' = 0.27843.$$

$$h = 40 + 0.27843 = 143.66. \text{ Ans.}$$

By logarithmic functions.

$$\log 40 = 1.60206$$

$$\log \sin 16^\circ - 10' = 9.44472$$

$$\text{Ans. } 143.66 \qquad 2.15734$$

Fig. 4.

Solution of any triangle.—The following principles, easily memorized, lead to the solution of any triangle, right or oblique.

Sides are proportional to sines of opposite angles(1)

$$\text{Thus, } \frac{\sin A}{a} = \frac{\sin B}{b} = \frac{\sin C}{c}.$$

Sin ang opp given side : sin ang opp req side :: given side : req side....(2)

$$\text{Thus, } \frac{\sin B}{\sin A} = \frac{\text{given side } b}{\text{required side } a}, \text{ in which } A, B \text{ and } b \text{ are given.}$$

Sum of sides : diff :: tang half sum of other two angles : tang half diff....(3)

$$\text{Thus, } \frac{b+c}{b-c} = \frac{\tan \frac{1}{2}(B+C)}{\tan \frac{1}{2}(B-C)}, \text{ in which } A, b \text{ and } c \text{ are given.}$$

The square of any side as $a^2 = b^2 + c^2 - 2bc \cos A$ (4)

$$\text{Thus, } \cos A = \frac{b^2 + c^2 - a^2}{2bc}, \text{ in which } a, b \text{ and } c \text{ are given.}$$

$$\sin \frac{1}{2}A = \sqrt{\frac{(s-b)(s-c)}{bc}}, \text{ in which } s = \frac{a+b+c}{2}, \text{ given.}$$

$$\tan \frac{1}{2}A = \sqrt{\frac{(s-b)(s-c)}{s(s-a)}}, \text{ in which } s = \frac{a+b+c}{2}, \text{ given.}$$

Rules in conjunction with the above:

Given: One side and two angles. Solve for "Req side" in (2).

Given: Two sides and angle opposite one of them. Solve for "Req side" and for one of the angles, in (2).

Given: Two sides and included angle. Solve for "Tang half diff" in (3).

Given: Three sides.

(a). Solve for $\cos A$, in (4), unless A is very small.

(b). Solve for $\sin \frac{1}{2}A$, in (4), unless A is very large.

(c). Solve for $\tan \frac{1}{2}A$, in (4), in general preferred.

If all the angles are required we may use the formulas:

$$\tan \frac{1}{2}A = \frac{r}{s-a}, \text{ in which } r = \sqrt{\frac{(s-a)(s-b)(s-c)}{s}};$$

$$\tan \frac{1}{2}B = \frac{r}{s-b}; \tan \frac{1}{2}C = \frac{r}{s-c}.$$

Circular Measure.—It is sometimes convenient in mathematical calculations to express angles in circular measure. The unit of circular measure is an angle subtended by an arc whose length is equal to the radius of the circle. The value of such an angle in common measure $= 57^\circ - 17' - 45'' = 57.2958^\circ$, called a radian. The number of radians in 180° is 3.141592, and as this value is equal to π we call $180^\circ = \pi$ in circular measure. Hence,

$$2\pi = 360^\circ$$

$$\pi = 180^\circ$$

$$\frac{\pi}{2} = 90^\circ.$$

Cubic Equations.—The general form of a cubic equation is

$$ax^3 + bx^2 + cx + d = 0 \dots\dots\dots (1)$$

Dividing by a , we have

$$x^3 + \frac{b}{a}x^2 + \frac{c}{a}x + \frac{d}{a} = 0 \dots\dots\dots (2)$$

By substitution, this can be reduced to the second general form

$$x^3 + Bx^2 + Cx + D = 0 \dots\dots\dots (3)$$

To eliminate x^2 , let $x = y - \frac{B}{3}$, then equation (3) reduces to

$$y^3 + y \left(C - \frac{B^2}{3} \right) + \left(\frac{2B^3}{27} - \frac{BC}{3} + D \right) = 0 \dots\dots\dots (4)$$

By substitution, this can be reduced to the third general form

$$y^3 + py + q = 0 \dots\dots\dots (5)$$

Now if we let $y = u + v$, equation (5) reduces to

$$u^3 + v^3 + (u+v)(3uv+p) + q = 0 \dots\dots\dots (6)$$

Whence, $3uv + p = 0$; $u^3 + v^3 + q = 0$; $u^3v^3 = -\frac{p^3}{27}$; and $u^3 + v^3 = -q$

And we have for the final equations

$$u^3 = -\frac{q}{2} + \sqrt{\frac{q^2}{4} + \frac{p^3}{27}} \dots\dots\dots (7)$$

$$v^3 = -\frac{q}{2} - \sqrt{\frac{q^2}{4} + \frac{p^3}{27}} \dots\dots\dots (8)$$

$$\text{Therefore } y = u + v = \sqrt[3]{-\frac{q}{2} + \sqrt{\frac{q^2}{4} + \frac{p^3}{27}}} + \sqrt[3]{-\frac{q}{2} - \sqrt{\frac{q^2}{4} + \frac{p^3}{27}}} \dots\dots\dots (9)$$

$$\text{And } x = y - \frac{B}{3} \text{ (see above). } \dots\dots\dots (10)$$

Note that the above is a purely algebraic solution, which can obtain only when $\frac{q^2}{4} + \frac{p^3}{27}$ is equal to or greater than 0. When $\frac{q^2}{4} + \frac{p^3}{27} < 0$ we have to resort to the trigonometric solution, following.

Trigonometric Solution.—In the equation, (9),

$$y = \sqrt[3]{-\frac{q}{2} + \sqrt{\frac{q^2}{4} + \frac{p^3}{27}}} + \sqrt[3]{-\frac{q}{2} - \sqrt{\frac{q^2}{4} + \frac{p^3}{27}}}$$

if $\frac{q^2}{4} + \frac{p^3}{27} < 0$, then the roots are imaginary and y is the sum of two imaginary quantities. To solve the equation for y , under these conditions, proceed as follows: Let $-\frac{q}{2} = n \cos \theta$, and $\frac{q^2}{4} + \frac{p^3}{27} = -n^2 \sin^2 \theta$; whence, $n = \sqrt{-\frac{p^3}{27}}$,

and $\cos \theta = -\frac{q}{2n}$. From this, the values of the three roots, y , are

$$2\sqrt{n} \cos \frac{\theta}{3}, \quad -2\sqrt{n} \cos \left(60^\circ - \frac{\theta}{3} \right), \quad 2\sqrt{n} \cos \left(120^\circ - \frac{\theta}{3} \right).$$

$$\text{And } x = y - \frac{B}{3}.$$

These calculations can be made readily by the use of logarithms. It is well to insert the value of x , thus found, in the original equation, (1), and solve as a check.

3.—Natural Sines, TANGENTS, COTANGENTS, COSINES.

(Versed sine = $1 - \cosine$; covered sine = $1 - \text{sine}$.)

*Log secant = colog cosine = 1 - log cosine; log cosecant = colog sine = 1 - log sine.

Ex.—Log sec 0° - 30° = 10.00002.

Ex.—Log cosec 0° - 30° = 12.05910

5.—Logarithmic Sines, TANGENTS, COTANGENTS, COSINES.

49°

*Log secant = colog cosine = 1 - log cosine; log cosecant = colog sine = 1 - log sine.

Ex.—Log sec 40°-30' = 10.11895. Ex.—Log cosec 40°-30' = 10.1874

8.—Logarithmic Sines, TANGENTS, COTANGENTS, COSINES.—(Cont'd.)

* Log sin A = log A (seconds) + S. Log tan A = log A (seconds) + T.

ERICAL TRIGONOMETRY.

—Spherical Trigonometry, in its broadest sense, of spherical pyramids; and, more directly, of the spherical pyramids.

ical pyramid (Fig. 1) is a triangular pyramid cut center of the sphere being the apex of the pyramid, face forming the base. The base is therefore bounded

les.
e is a term applied to the outline of the base of a amid; thus, Fig. 1, $A B C A$ is a spherical triangle. Trigonometry are confined usually to the solution of the practical application leads us into the fields of and Astronomy.

ctions or quantities in any follows (Fig. 1): Radius, r ;

...	A	B	C
...	a	b	c
...	a_1	b_1	c_1

us as unity, and remember-
cles are proportional to the
angles, it is seen that the
to six *primary* functions,
l angles A, B, C , and the
Three of these must be
ve the other three. The
 c , are always shown on the
s in Figs. 2 and 3.

l Triangles.—The spherical
is a right spherical triangle,
e and o the center of the
g formulas are given for
triangles.

Formulas:

$$\frac{\sin B}{\sin b} = \frac{\sin C}{\sin c} = \frac{\cos A}{\cos a}.$$

$$\tan A = \frac{\tan a}{\sin b}, \quad \cos B = \frac{\tan a}{\tan c}, \quad \tan B = \frac{\tan b}{\sin a}$$

$$\cos c = \cot A \cot B.$$

ormulas are all that are necessary, as the value of
may be determined by transposition. Thus, from
e, $\sin a = \frac{\tan b}{\tan B}$, and so on.

the side b if the angle $A = 18^\circ - 20'$ and the hypoth-

$A = \frac{\tan b}{\tan c}$, we have, $\tan b = \tan c \cos A$;

$\log \tan 48^\circ - 30' = 0.05319$

$\log \cos 18^\circ - 20' = 9.97738$

gle $b = 47^\circ - 01'$, as $0.03057 = \log \tan b$.

e (arc) b may be obtained from the table of Circular
ollowing).

Fig. 1.

Fig. 2.

Oblique Spherical Triangles.—

Fig. 3.

Formulas.

$$\frac{\sin A}{\sin B} = \frac{\sin a}{\sin b}, \quad \frac{\sin B}{\sin C} = \frac{\sin b}{\sin c}, \quad \frac{\sin A}{\sin C} = \frac{\sin a}{\sin c}.$$

$$\begin{aligned} \cos a &= \cos b \cos c + \sin b \sin c \cos A, \\ \cos b &= \cos c \cos a + \sin c \sin a \cos B, \\ \cos c &= \cos a \cos b + \sin a \sin b \cos C, \\ \cos A &= -\cos B \cos C + \sin B \sin C \cos a, \\ \cos B &= -\cos C \cos A + \sin C \sin A \cos b, \\ \cos C &= -\cos A \cos B + \sin A \sin B \cos c. \end{aligned}$$

$$\sin \frac{1}{2} A = \sqrt{\frac{\sin(s-b) \sin(s-c)}{\sin b \sin c}}$$

$$\sin \frac{1}{2} B = \sqrt{\frac{\sin(s-c) \sin(s-a)}{\sin c \sin a}}$$

$$\sin \frac{1}{2} C = \sqrt{\frac{\sin(s-a) \sin(s-b)}{\sin a \sin b}}$$

$$\cos \frac{1}{2} A = \sqrt{\frac{\sin s \sin(s-a)}{\sin b \sin c}}$$

$$\cos \frac{1}{2} B = \sqrt{\frac{\sin s \sin(s-b)}{\sin c \sin a}}$$

$$\cos \frac{1}{2} C = \sqrt{\frac{\sin s \sin(s-c)}{\sin a \sin b}}$$

$$\tan \frac{1}{2} A = \sqrt{\frac{\sin(s-b) \sin(s-c)}{\sin s \sin(s-a)}}$$

$$\tan \frac{1}{2} B = \sqrt{\frac{\sin(s-c) \sin(s-a)}{\sin s \sin(s-b)}}$$

$$\tan \frac{1}{2} C = \sqrt{\frac{\sin(s-a) \sin(s-b)}{\sin s \sin(s-c)}}$$

$$\sin \frac{1}{2} a = \sqrt{-\frac{\cos S \cos(S-A)}{\sin B \sin C}}$$

$$\sin \frac{1}{2} b = \sqrt{-\frac{\cos S \cos(S-B)}{\sin C \sin A}}$$

$$\sin \frac{1}{2} c = \sqrt{-\frac{\cos S \cos(S-C)}{\sin A \sin B}}$$

$$\cos \frac{1}{2} a = \sqrt{\frac{\cos(S-B) \cos(S-C)}{\sin B \sin C}}$$

$$\cos \frac{1}{2} b = \sqrt{\frac{\cos(S-C) \cos(S-A)}{\sin C \sin A}}$$

$$\cos \frac{1}{2} c = \sqrt{\frac{\cos(S-A) \cos(S-B)}{\sin A \sin B}}$$

$$\tan \frac{1}{2} a = \sqrt{\frac{\cos S \cos(S-A)}{\cos(S-B) \cos(S-C)}}$$

$$\tan \frac{1}{2} b = \sqrt{\frac{\cos S \cos(S-B)}{\cos(S-C) \cos(S-A)}}$$

$$\tan \frac{1}{2} c = \sqrt{\frac{\cos S \cos(S-C)}{\cos(S-A) \cos(S-B)}}$$

Note.—In the above formulas, $s = \frac{1}{2}(a+b+c)$; $S = \frac{1}{2}(A+B+C)$.

$$\frac{\sin \frac{1}{2}(A+B)}{\sin \frac{1}{2}(A-B)} = \frac{\tan \frac{1}{2} c}{\tan \frac{1}{2}(a-b)}$$

$$\frac{\sin \frac{1}{2}(a+b)}{\sin \frac{1}{2}(a-b)} = \frac{\cot \frac{1}{2} C}{\tan \frac{1}{2}(A-B)}$$

$$\frac{\cos \frac{1}{2}(A+B)}{\cos \frac{1}{2}(A-B)} = \frac{\tan \frac{1}{2} c}{\tan \frac{1}{2}(a+b)}$$

$$\frac{\cos \frac{1}{2}(a+b)}{\cos \frac{1}{2}(a-b)} = \frac{\cot \frac{1}{2} C}{\tan \frac{1}{2}(A+B)}$$

General Rules.

1. Sines of the sides are proportional to the sines of their opposite angles. Example.—In Fig. 2, $\sin A : \sin a :: \sin C : \sin c$.
2. Cosine of any side equals the product of the cosines of the other two sides, plus the product of their sines and the cosine of their included angle. Example.—In Fig. 2, $\cos a = \cos b \cos c + \sin b \sin c \cos A$.

Special Cases.

Case I. Given one side (c) and two adjacent angles (A and B).

1st. Solve for b and c in the following:

$$\tan \frac{1}{2}(b-a) = \sin \frac{1}{2}(B-A) \operatorname{cosec} \frac{1}{2}(B+A) \tan \frac{1}{2} c.$$

$$\tan \frac{1}{2}(b+a) = \cos \frac{1}{2}(B-A) \sec \frac{1}{2}(B+A) \tan \frac{1}{2} c.$$

2nd. Solve for C in the following:

$$\cot \frac{1}{2} C = \sin \frac{1}{2}(b+a) \operatorname{cosec} \frac{1}{2}(b-a) \tan \frac{1}{2}(B-A).$$

Case II. Given two sides (b and c) and their included angle (A).

1st. Solve for B and C in the following:

$$\tan \frac{1}{2}(B-C) = \sin \frac{1}{2}(b-c) \operatorname{cosec} \frac{1}{2}(b+c) \cot \frac{1}{2}A;$$

$$\tan \frac{1}{2}(B+C) = \cos \frac{1}{2}(b-c) \sec \frac{1}{2}(b+c) \cot \frac{1}{2}A.$$

2nd. Solve for a in the following:

$$\tan \frac{1}{2}a = \sin \frac{1}{2}(B+C) \operatorname{cosec} \frac{1}{2}(B-C) \tan \frac{1}{2}(b-c).$$

Case III. Given the three sides (a , b and c). Solve for A , B and C .

$$\tan \frac{1}{2}A = \frac{k}{\sin(s-a)}; \tan \frac{1}{2}B = \frac{k}{\sin(s-b)}; \tan \frac{1}{2}C = \frac{k}{\sin(s-c)};$$

$$\text{in which } k = \sqrt{\frac{\sin(s-a) \sin(s-b) \sin(s-c)}{\sin s}},$$

$$\text{and } s = \frac{1}{2}(a+b+c).$$

Case IV. Given the three angles (A , B and C). Solve for a , b and c .

$$\tan \frac{1}{2}a = K \cos(S-A); \tan \frac{1}{2}b = K \cos(S-B); \tan \frac{1}{2}c = K \cos(S-C);$$

$$\text{in which } K = \sqrt{\frac{\cos S}{-\cos(S-A) \cos(S-B) \cos(S-C)}},$$

$$\text{and } S = \frac{1}{2}(A+B+C).$$

Case V. Given two sides (a and b) and the angle (B) opposite one of them.

1st. Solve for A in the following:

$$\sin A = \sin a \operatorname{cosec} b \sin B.$$

2nd. Solve for C and c in the following:

$$\cot \frac{1}{2}C = \sin \frac{1}{2}(b+a) \operatorname{cosec} \frac{1}{2}(b-a) \tan \frac{1}{2}(B-A);$$

$$\tan \frac{1}{2}c = \sin \frac{1}{2}(B+A) \operatorname{cosec} \frac{1}{2}(B-A) \tan \frac{1}{2}(b-a).$$

Case VI. Given two angles (A and B) and the side (b) opposite one of them.

1st. Solve for a in the following:

$$\sin a = \sin A \operatorname{cosec} B \sin b.$$

2nd. Solve for c and C in the following:

$$\tan \frac{1}{2}c = \sin \frac{1}{2}(B+A) \operatorname{cosec} \frac{1}{2}(B-A) \tan \frac{1}{2}(b-a);$$

$$\cot \frac{1}{2}C = \sin \frac{1}{2}(b+a) \operatorname{cosec} \frac{1}{2}(b-a) \tan \frac{1}{2}(B-A).$$

Distance between two points on the Earth's surface.—Given the latitudes and longitudes of two points B and C , Fig. 4, let it be required to find the shortest distance, a , between them. Select a third point, A , at the nearest pole; and connect the points ABC with arcs of great circles. Produce the meridian lines AB and AC to the equator. Then will P' be the latitude of C ; P' , the latitude of B ; and L , the difference of longitude; and, in the spherical triangle ABC , $b = 90^\circ - P'$, $c = 90^\circ - P$, and the angle $A = L$. Solve for Case II, preceding.

Fig. 4.

The Celestial Sphere.—In solving astronomical problems, the center of the earth is assumed to be the center of the celestial sphere; and its axis produced, the axis of said sphere. The extremities of the axis produced are the poles; and the great circle whose plane is perpendicular to the axis (at the center), is the equator. A plumb line at any given point is called the vertical line, and if produced it intersects the celestial sphere in the zenith (above) and in the nadir (below). The zenith and nadir are the poles of any vertical line; and a great circle whose plane is perpendicular to said vertical line, forms the horizon. The meridian is the great circle whose plane passes through the zenith and the poles, and the points where it intersects the horizon are called the north and south points. The prime vertical is the great circle whose plane passes through the zenith perpendicular to the meridian, and the points where it intersects the horizon are called the east and west points.

A vertical circle is a great circle whose plane passes through the poles of a vertical line, i. e., through the zenith and nadir. It is therefore perpendicular to the horizon. The azimuth of a star is the arc measured on the horizon between the north point (or the south point) and the vertical circle passing through the star; hence it is the tangential angle at the zenith, between the meridian and said vertical circle. The altitude, h , of a star is

its distance from the horizon measured on a vertical circle. The *zenith distance* = $z = 90^\circ - h$.

An *hour circle* is any great circle whose plane passes through the poles (and perpendicular to the equator). The *hour angle*, P , of any star is the tangential angle which its hour circle measures (*westward* from and) with the meridian, at the pole; the arc of the angle is measured at the equator. The *right ascension*, $R. A.$, of a star is the distance on the equator from the *vernal equinox* (the point where the sun crosses the equator from south to north*), *eastward* to the hour circle of the star. The *declination*, δ , of a star is its distance from the equator, measured on an hour circle. The *polar distance*, p , = $90^\circ - \delta$.

Astronomical Time.—A *solar day* is our common day of twenty-four hours. Any particular solar day is an *apparent solar day*, and is the interval between two successive passages of the sun across the same meridian. A *mean solar day* is the average length of the solar days in a *tropical year*. A tropical year contains, according to Hansen and Olufsen, 365.2422008 mean solar days; according to Bessel, 365.24222 mean solar days. On account of the earth's revolution around the sun, there is *one more sidereal day* in a year than solar days. Hence, according to Bessel there are 366.24222 sidereal days in a year, and we have the ratios—

1 solar day = 1.0027379 sidereal day = 1 sid. day + 3^m 56.555^s sid. time.
1 sid. day = 0.9972696 solar day = 1 solar day - 3^m 55.909^s solar time.

The *equation of time* is the quantity (time) to be "added," algebraically, to the *apparent solar time* to give the *mean solar time*. Its value for any day of the year may be found in the *solar ephemeris* tables of the Nautical Almanac.

The following are conversion tables for *mean solar time* and *sidereal time*:

1.—MEAN SOLAR TIME REDUCED TO SIDEREAL TIME.

Mean Hours	Sidereal Time		Mean Minutes	Sidereal Time		Mean Seconds	Sidereal Time
1	1h	0m	9.856s	1	1m	0.164s	1.003s
2	2	0	19.713	2	2	0.329	2.005
3	3	0	29.569	3	3	0.493	3.008
4	4	0	39.426	4	4	0.657	4.011
5	5	0	49.282	5	5	0.821	5.014
6	6	0	59.139	6	6	0.986	6.016
7	7	1	8.995	7	7	1.150	7.019
8	8	1	18.852	8	8	1.314	8.022
9	9	1	28.708	9	9	1.478	9.025
10	10	1	38.565	10	10	1.643	10.027
24	24	8	56.555	30	30	4.928	30.082

2.—SIDEREAL TIME REDUCED TO MEAN SOLAR TIME.

Sidereal Hours	Mean Solar Time.		Sidereal Minutes	Mean Solar Time		Sidereal Seconds	Mean Solar Time
1	0h	59m	50.170s	1	0m	59.836s	0.997s
2	1	59	40.341	2	1	59.672	1.995
3	2	59	30.511	3	2	59.509	2.992
4	3	59	20.682	4	3	59.345	3.989
5	4	59	10.852	5	4	59.181	4.986
6	5	59	1.023	6	5	59.017	5.984
7	6	58	51.193	7	6	58.853	6.981
8	7	58	41.364	8	7	58.689	7.978
9	8	58	31.534	9	8	58.526	8.975
10	9	58	21.704	10	9	58.362	9.973
24	23	56	4.091	30	29	55.085	29.918

* The *autumnal equinox* is the point where the sun crosses the equator from north to south.

11.—MENSURATION.

A.—PLANE SURFACES, LINES, ETC.

Triangle.—Three sides. $Area = \frac{bh}{2}$; $= \frac{1}{2} ab \sin C$;

$= \sqrt{s(s-a)(s-b)(s-c)}$, in which $s = \frac{a+b+c}{2}$. Length of

$c = \sqrt{a^2 + b^2 + 2ab \cos C}$. Center of gravity is $\frac{h}{3}$ above b .

Angles $A + B + C = 180^\circ$.

Right-angled triangle.—Angle $C = 90^\circ$. $Area = \frac{ab}{2}$. Hypoth-

Fig. 1.

enuse $c = \sqrt{a^2 + b^2}$; hence $a = \sqrt{c^2 - b^2} = \sqrt{(c+b)(c-b)}$; $b = \sqrt{c^2 - a^2}$.

If $a = b$, then $c = 1.4142 a = 1.4142 b$, or $a = b = 0.7071 c$.

Acute-angled triangle.—Each angle less than 90° .

Obtuse-angled triangle.—One angle greater than 90° (as Fig. 1).

Isosceles triangle.—Two sides (therefore two angles) equal.

Equilateral triangle.—Three sides (therefore three angles) equal. See Table 1, Regular Polygons.

Fig. 2.

Fig. 3.

Fig. 4.

Quadrilateral.—Four Sides.

Trapezium.—An irregular quadrilateral; no two sides parallel. $Area$ may be obtained by cutting it into two triangles, and solving.

Trapezoid.—Two sides only, parallel, Fig. 2. $Area = \frac{h}{2} (b + b_1)$. See

Section 29 for center of gravity.

Parallelogram.—Includes the rhomboid, rhombus, rectangle and square.

$Area$ = length of one side multiplied by perpendicular distance to parallel side opposite.

Rhomboid.—A "skewed" rectangle, Fig. 3; opposite sides (therefore opposite angles) equal. $Area = bh = ba \sin A = ab \sin A = ah_1$ (Fig. 3).

$Cen.$ of grav is at intersection of two diagonals.

Rectangle.—Opposite sides equal and parallel, as with the rhomboid; but angles 90° , Fig. 4. Side $b > a$. $Area = ab$. Diagonal $= \sqrt{a^2 + b^2}$. $Cen.$ of grav. equi-distant from parallel sides, and at intersection of diagonals.

Fig. 5.

Fig. 6.

Rhombus.—Same as rhomboid (Fig. 3) but with all sides equal, Fig. 5. $Area = bh = b^2 \sin A$.

Square.—All sides equal; angles 90° , Fig. 6. $Area = b^2$. Diagonal $= \sqrt{2} b^2 = 1.4142 b$. Side b = diagonal $\times 0.7071$.

Regular Polygon.—Any number of sides, from the triangle, with three sides, to the circle, with an ∞ number of sides. In Table 1, following,

s = length of each side = $2 R \sin \frac{1}{2} \alpha = 2 r \tan \frac{1}{2} \alpha$;
 n = number of sides in polygon ($n s$ = perimeter);
 R = radius of circumscribing circle = $\frac{1}{2} s \operatorname{cosec} \frac{1}{2} \alpha = r \sec \frac{1}{2} \alpha$;
 r = apothem = radius of inscribed circle = $R \cos \frac{1}{2} \alpha = \frac{1}{2} s \cot \frac{1}{2} \alpha$;
 α = angle subtended from center by each side = $360^\circ / n$;
 β = internal angle = $180^\circ - \alpha$;

$$\text{Area} = \frac{s r n}{2} = \frac{\text{perimeter} \times \text{apothem}}{2} = \frac{1}{2} n s R \cos \frac{1}{2} \alpha = n r^2 \tan \frac{1}{2} \alpha.$$

Circle.—Infinite number of sides.

Circumference, $p = \pi d = 3.1416 d$, $= 2 \pi r = 6.2832 r$;

Area, $a = \frac{\pi d^2}{4} = 0.7854 d^2$, $= \pi r^2 = 3.1416 r^2$;

Diameter, $d = \frac{p}{\pi} = 0.318310 p$, $= 2 \sqrt{\frac{a}{\pi}} = 1.12838 \sqrt{a}$;

Radius, $r = \frac{p}{2 \pi} = 0.159155 p$, $= \sqrt{\frac{a}{\pi}} = 0.56419 \sqrt{a}$.

Problem.—Find the length of circular arc corresponding to a central angle of $237^\circ - 46' - 58.3''$ and to a radius of 6387.42.

Solution.—From Table 2.

200°	=	3.490659
30°	=	.523599
7°	=	.122173
40'	=	.011636
6'	=	.001745
50"	=	.000242
8"	=	.000039
.3"	=	.000001

log	4.150094	=	0.6180580
log	6387.42	=	3.8053255

Ans. 26508.4 4.4233835

Table 3, following, has been prepared from Table 2.

VALUES OF α_1 AND β_1 (Fig. 9)

3.—LENGTHS OF CIRCULAR ARCS FOR RADIUS 1.

(Deg., Min., Sec., are central angles; Length is length of subtended arc.)

Ex.—For a chord of 215 ft. and rise of 18 ft.: The rise + chord = 0.083721; and the corresponding arc = $215 \times (1.01828 + .721 \times .00044) = 215 \times 1.0186 = 219.00$ ft. Ans.

Fig. 10.

Flat Circular Arc.—

Exact formulas:

$$c_2 = \text{chord of half arc} = \sqrt{h^2 + \left(\frac{c}{2}\right)^2} = \frac{c}{2} \sec \frac{1}{2} \alpha;$$

$$e = \text{external secant} = r (\sec \frac{1}{2} \alpha - 1) = r (\text{exsec } \frac{1}{2} \alpha)$$

$$t = \text{tangent distance} = r \tan \frac{1}{2} \alpha = \frac{c}{2} \sec \frac{1}{2} \alpha.$$

Approximate formulas:

$$a = \text{arc} = \frac{8c_2 - c}{3}; \quad h_x = \frac{x(c-x)}{2r} = \frac{4hx}{c^2}(c-x);$$

$$c = \text{chord} = 8c_2 - 8a; \quad h_1 = \text{quarter ordinate} = \frac{1}{4}h \left(\text{when } x = \frac{c}{4} \right);$$

$$e = h; \quad t = \frac{c}{2} \sqrt{\frac{c^2}{4r^2} + 1};$$

$$h = \text{rise} = \frac{c^2}{8r} \left(\therefore r = \frac{c^2}{8h} \right); \quad y_1 = \frac{1}{4}h. \quad (g = \text{cen. of grav. of arc.})$$

The coefficients in Table 5 (a and b), following, give an idea of the approximation of the above formulas; and they will also be found convenient to use in some cases where fairly correct values, simply, are sought.

5.—COEFFICIENTS TO BE USED WITH APPROXIMATE FORMULAS (Page, preceding) TO GIVE EXACT VALUES. (Fig. 10.)

(a)—BASED ON CENTRAL ANGLE $\alpha = 10^\circ, 20^\circ, 30^\circ$, etc.

(Note.—Multiply result from approximate formula, by Coefficient.)

Central Angle $\alpha =$	10°	20°	30°	40°	50°	60°
Values of $\frac{h}{c} =$	.02183	.04374	.06583	.08816	.11085	.13397
Values of $\frac{a}{c} =$	1.00127	1.00510	1.01152	1.02060	1.03245	1.04720
Values of $\frac{c}{a} =$	.99873	.99493	.98862	.97982	.96857	.95493
Values of $\frac{c}{r} =$	.17431	.34730	.51764	.68404	.84524	1.00000
Formulas.	Coefficients.*					
$a = \frac{8c_2 - c}{3} \times$	1.00000	1.00000	.99999	.99997	.99992	.99984
$c = (8c_2 - 3a) \times$	1.00000	.99999	.99997	.99991	.99977	.99951
$\dagger e = h \times$	1.00382	1.01543	1.03528	1.06418	1.10338	1.15470
$\dagger h = \frac{c^2}{8r} \times$	.99810	.99240	.98296	.96985	.95315	.93301
$\dagger h_1 = \frac{1}{2}h \times$	1.00017	1.00064	1.00143	1.00256	1.00401	1.00581
$\dagger h_2 = \frac{1}{2}h \times$	1.00050	1.00191	1.00429	1.00765	1.01199	1.01733
$\dagger y_1 = \frac{1}{2}h \times$	1.00014	1.00052	1.00116	1.00204	1.00321	1.00464

* Coefficient for $a = \frac{1}{2} \cdot \frac{8 \sin \frac{1}{2} \alpha - \sin \frac{1}{2} \alpha}{\text{arc}}$; for $c = \frac{8 \sin \frac{1}{2} \alpha - 1 \frac{1}{2} \text{ arc}}{\sin \frac{1}{2} \alpha}$;
 for $e = \sec \frac{1}{2} \alpha$; for $h = \cos^2 \frac{1}{2} \alpha$; for $h_1 = \frac{1}{2} \cdot \frac{1 - \cos \frac{1}{2} \alpha}{\cos \frac{1}{2} \alpha - \cos \frac{1}{2} \alpha}$;
 for $h_2 = \frac{4(1 - \cos \frac{1}{2} \alpha)}{1 - \cos \frac{1}{2} \alpha}$; for $y_1 = \frac{1}{2} \cdot \frac{1 - \cos \frac{1}{2} \alpha}{\frac{c}{a} - \cos \frac{1}{2} \alpha}$.

† Increase in coefficient is nearly parabolic; that is, nearly proportional to α^2 ; thus, the coefficient of h_1 for $\alpha = 18^\circ$, is $1 + .00064 \times \frac{(18)^2}{(20)^2} = 1.00052$, using the coefficient of the nearest angle.

‡ Decrease in coefficient is nearly parabolic.

A.—COEFFICIENTS TO BE USED WITH APPROXIMATE FORMULAS.—Concluded.

(b) BASED ON RISE TO CHORD, $\frac{h}{c}$, OF ARC.

(Note.—Multiply result from approximate formula, by Coefficient.)

Values of $\frac{h}{c} =$	.02	.04	.06	.08	.10	.12
Values of $\alpha =$	9° 09' 45"	18° 17' 44"	27° 22' 16"	36° 21' 40"	45° 14' 23"	53° 58' 59"
Values of $\frac{r}{c} =$	6.3	3.1	2.1	1.6	1.3	1.1
Values of $\frac{c}{r} =$	.16	.32	.47	.62	.77	.91
Formulas.	Coefficients.					
$\uparrow r = h \quad \times$	1.003	1.013	1.029	1.052	1.083	1.122
$\downarrow h = \frac{c^2}{8r} \quad \times$	.998	.994	.986	.975	.962	.946
$\uparrow h_1 = \frac{1}{2}h \quad \times$	1.000	1.001	1.001	1.002	1.003	1.005
$\uparrow h_2 = \frac{1}{4}h \quad \times$	1.0004	1.0016	1.0036	1.0063	1.0098	1.0140

† Increase in coefficient is nearly parabolic.

‡ Decrease in coefficient is nearly parabolic.

Fig. 11.

Circular Segment; and Half Segment.—Diameter $d = 2r$.

Point g = position of center of gravity of segment A
 G_1 = position of center of gravity of segment B
 G = position of center of gravity of the whole segment
 G_1 = position of center of gravity of the whole segment

$\left\{ \begin{array}{l} \text{segment A} \\ \frac{1}{2} \text{ (segment A)} \end{array} \right\}$ with coordinates $\left\{ \begin{array}{l} x=0; y=y_0. \\ x=x_0; y=y_0. \\ x=0; y=Y_0. \\ x=X_0; y=Y_0. \end{array} \right.$

Formulas for Center of Gravity (Fig. 11):

(Geometrical)

$$\begin{aligned} \text{For smaller segment: } \left\{ \begin{array}{l} x_0 = \frac{1}{3} r \frac{4\sin^2 \frac{1}{2} \alpha - \sin^2 \frac{1}{2} \alpha \cos \frac{1}{2} \alpha}{\frac{1}{2} \alpha_1 - \sin \frac{1}{2} \alpha \cos \frac{1}{2} \alpha} = \frac{1}{3} r \frac{c^2 - \frac{c^2}{4} (r-h)}{\text{area A of segment}} \\ y_0 = \frac{1}{3} r \frac{\sin^2 \frac{1}{2} \alpha}{\frac{1}{2} \alpha_1 - \sin \frac{1}{2} \alpha \cos \frac{1}{2} \alpha} = \frac{1}{3} r \frac{c^2}{\text{area A of segment}} \end{array} \right. \\ \alpha = 0^\circ \text{ to } 180^\circ \\ \text{For larger segment: } \left\{ \begin{array}{l} X_0 = \frac{1}{3} r \frac{4\sin^2 \frac{1}{2} \beta + \sin^2 \frac{1}{2} \beta \cos \frac{1}{2} \beta}{\frac{1}{2} \beta_1 + \sin \frac{1}{2} \beta \cos \frac{1}{2} \beta} = \frac{1}{3} r \frac{c^2 + \frac{c^2}{4} (H-r)}{\text{area B of segment}} \\ Y_0 = \frac{1}{3} r \frac{\sin^2 \frac{1}{2} \beta}{\frac{1}{2} \beta_1 + \sin \frac{1}{2} \beta \cos \frac{1}{2} \beta} = \frac{1}{3} r \frac{c^2}{\text{area B of segment}} \end{array} \right. \\ \beta = 180^\circ \text{ to } 360^\circ \end{aligned}$$

$$\text{Or, } y_0 = \frac{c^2}{12A}; Y_0 = \frac{c^2}{12B}; \frac{y_0}{Y_0} = \frac{B}{A} \text{ when } \alpha + \beta = 360^\circ.$$

Note that $\sin \frac{1}{2} \alpha = \sin \frac{1}{2} \beta$; $\cos \frac{1}{2} \alpha = -\cos \frac{1}{2} \beta$; but $\sin \frac{1}{2} \alpha = \cos \frac{1}{2} \beta$, etc. Table 6, below, gives tabular values.

6.—VALUES (COEFFICIENTS) OF x_0 , y_0 , X_0 AND Y_0 FOR VARIOUS VALUES OF α AND β . (Fig. 11.)

(Multiply the tabular Coefficient by the radius.)

α	$x_0 = \frac{c^2}{12A}$ times	$y_0 = \frac{c^2}{12B}$ times	β	$X_0 = \frac{c^2}{12B}$ times	$Y_0 = \frac{c^2}{12A}$ times	α	$x_0 = \frac{c^2}{12A}$ times	$y_0 = \frac{c^2}{12B}$ times	β	$X_0 = \frac{c^2}{12B}$ times	$Y_0 = \frac{c^2}{12A}$ times
0°	.00000	Unity	360°	.42441	.00000	120°	.33920	.70502	240°	.44162	.17133

$\frac{1}{2}(r+h)$; $h = r - \sqrt{r^2 - \frac{c^2}{4}}$; $c = 2\sqrt{h(2r-h)}$. If the segment is a semi-circle and we denote the rise by $H (= 2r-h)$,

$H = r + \sqrt{r^2 - \frac{c^2}{4}}$; $c = 2\sqrt{H(2r-H)}$. The area of a segment is a semi-circle, i. e., with rise H , = area of circle $(3.1416 r^2)$ rise $h (= 2r-H)$.

8.—*AREAS OF SEGMENTS OF CIRCLES FOR DIAMETER 1.

To find the area of any circular segment: Multiply the tabular area below, corresponding to the particular value of rise + diam., by the square of the diam.

Note that the *diam.* = rise + (half chord)² + rise; hence, (*diam.*)² = $\left[\frac{1 + (\text{half chord})^2}{\text{rise}} \right]^2$; and, rise + *diam.* = rise² + [rise² + (half chord)²].

Rise + Diam.	Thousandths.

*Calculated from formula: Area $A = 0.3926990817 - \left[x(r^2 - x^2)^{\frac{1}{2}} + r^2 \sin^{-1} \frac{x}{r} \right]$
in which r = radius of circle, and x = radius - rise = $0.5 - \text{rise}$.

Note that $\sin^{-1} \frac{x}{r}$ = the angle (in *circular measure*) whose natural sine $\frac{x}{r}$. For angles reduced to circular measure, see Tables 2 and 3.

Circular Ring; and Half Circular Ring.—

Let R = radius of outer circle = $\frac{D}{2}$;

r = radius of inner circle = $\frac{d}{2}$;

R_0 = radius of circle with area equivalent to that circular ring;

A = area of circular ring; $\pi = 3.1416$.

Fig. 12.

$$\text{Then } R_0 = \sqrt{R^2 - r^2} = \sqrt{(R+r)(R-r)} = \frac{1}{2} \sqrt{(D+d)(D-d)} = \sqrt{\frac{A}{\pi}};$$

$$A = \pi R^2 - \pi(r^2) = \pi(R+r)(R-r) = \frac{\pi}{4}(D^2 - d^2) = \frac{\pi}{4}(D+d)(D-d);$$

$$R = \sqrt{r^2 + \frac{A}{\pi}} = \sqrt{r^2 + R_0^2}; \quad D = \sqrt{d^2 + \frac{4A}{\pi}};$$

$$r = \sqrt{R^2 - \frac{A}{\pi}} = \sqrt{R^2 - R_0^2}; \quad d = \sqrt{D^2 - \frac{4A}{\pi}}.$$

Formula for Center of Gravity (Fig. 12):

$$\text{For half circular ring, } x_0 = \frac{0.42441(R^2 - r^2)}{(R^2 - r^2)} = \frac{0.21221(D^2 - d^2)}{(D^2 - d^2)} = \text{distance to cen. of grav. g.}$$

The above value of x_0 may be obtained from Pappus's Theorem, page 243, by using it inversely. Thus, we know that the volume generated by the revolution of a plane area (lying wholly on one side of an axis) about its axis = the area $\times$ the path described by its center of gravity. Hence, volume $V = 2\pi x_0 A$; or

$$x_0 = \frac{V}{2\pi A} = \frac{\text{volume of spherical shell}}{2\pi \cdot \text{Area of half circular ring}} = \frac{1}{2\pi} \cdot \frac{\frac{4}{3}\pi(R^3 - r^3)}{\frac{\pi}{2}(R^2 - r^2)}$$

$$= \frac{4}{3\pi} \cdot \frac{R^3 - r^3}{R^2 - r^2}; \text{ in which } \frac{4}{3\pi} = 0.42441.$$

Pappus's Theorem is useful in finding the centers of gravity of any figures (lines or areas) of revolution.

Zone, and Half Zone, of Circle.—

Area of zone = Z = area of circle ($3.1416 r^2$) $-(A+B)$; in which r = radius of circle, A = area of upper segment, and B = area of lower segment. (See preceding tables and formulas for areas of segments.)

Formulas for Center of Gravity (Fig. 13):

Let g = cen. of grav. of zone, with coordinates $x=0, y=y_0$;

g_1 = cen. of grav. of half zone, with coordinates $x=x_0, y=y_0$;

A = area of upper segment, with cen. of grav. dist. y_a from axis X_1-X_1 ;

Z = area of zone, with cen. of grav. distant y_0 from X_1-X_1 ;

B = area of lower segment, with cen. of grav. dist. y_b from X_1-X_1 ;

C = area of circle ($=3.1416 r^2$), with cen. of grav. distant r from X_1-X_1 ;

Fig. 13.

$$\text{Then, } x_0 = \frac{0.42441 r C - A x_a - B x_b}{Z};$$

$$y_0 = y_c - r = \frac{C r - A y_a - B y_b}{Z} - r.$$

Ordinates x_a, x_b, y_a and y_b may be solved by use of formulas in connection with Fig. 11.

Fig. 14.

Circular Lune (Fig. 14).—

Area A = area of segment with rise h minus area of segment with rise h' .
(Common chord c .)

See preceding Tables, 7 and 8, of Circular Segments.

Circular Sector; and Half Sector (Fig. 15).—

Point g = position of center of gravity of sector A
 G_1 = position of center of gravity of sector B
 G = position of center of gravity of half sector
 G_1 = position of center of gravity of half sector

with coordinates $\left\{ \begin{array}{l} x=0; y=y_0 \\ x=x_0; y=y_0 \\ x=0; y=Y_0 \\ x=X_0; y=Y_0 \end{array} \right.$

Formulas for Center of Gravity and Area (Fig. 15):

$$y_0 = \frac{1}{3} r \frac{\sin \frac{1}{2} \alpha}{\frac{1}{2} \alpha_1} = \frac{1}{3} r \frac{\sin \frac{1}{2} \alpha}{\alpha_1} = \frac{1}{3} r^2 \frac{\sin \frac{1}{2} \alpha}{a} = \frac{1}{3} r^2 \frac{\sin \frac{1}{2} \alpha}{A}$$

$$x_0 = y_0 \tan \frac{1}{2} \alpha = \frac{1}{3} r \frac{\text{vers } \frac{1}{2} \alpha}{\alpha_1} = \frac{1}{3} r^2 \frac{\text{vers } \frac{1}{2} \alpha}{a} = \frac{1}{3} r^2 \frac{\text{vers } \frac{1}{2} \alpha}{A}$$

$$Y_0 = \frac{1}{3} r \frac{\sin \frac{1}{2} \beta}{\frac{1}{2} \beta_1} = \frac{1}{3} r \frac{\sin \frac{1}{2} \beta}{\beta_1} = \frac{1}{3} r^2 \frac{\sin \frac{1}{2} \beta}{b} = \frac{1}{3} r^2 \frac{\sin \frac{1}{2} \beta}{B}$$

$$X_0 = Y_0 \tan \frac{1}{2} \beta = \frac{1}{3} r \frac{\text{vers } \frac{1}{2} \beta}{\beta_1} = \frac{1}{3} r^2 \frac{\text{vers } \frac{1}{2} \beta}{b} = \frac{1}{3} r^2 \frac{\text{vers } \frac{1}{2} \beta}{B}$$

$$\text{Area A} = \frac{1}{2} r^2 \alpha_1 = \frac{1}{2} a r = \frac{1}{3} r^2 \frac{\sin \frac{1}{2} \alpha}{y_0} = \frac{1}{3} r^2 \frac{\text{vers } \frac{1}{2} \alpha}{x_0}$$

$$\text{Area B} = \frac{1}{2} r^2 \beta_1 = \frac{1}{2} b r = \frac{1}{3} r^2 \frac{\sin \frac{1}{2} \beta}{Y_0} = \frac{1}{3} r^2 \frac{\text{vers } \frac{1}{2} \beta}{X_0}$$

In which a = length of arc of sector of area A and central angle α ,

b = length of arc of sector of area B and central angle β ,

$\alpha_1 = .0174533 \alpha$ (degrees), (See Tables 2 and 3 of length of circular arcs to radius 1.)

$\beta_1 = .0174533 \beta$ (degrees).

Relations of Circle and Square.—

Let D = diam. of circle; C = circum. of circle; A = area of circle.

d = diag. of square; s = side of square; p = perimeter of square;

a = area of square.

$$\text{Then, } D = \frac{C}{\pi} = \frac{4A}{C}; C = \pi D = \frac{4A}{D}; A = \frac{\pi}{4} D^2 = \frac{CD}{4} = \frac{C^2}{4\pi};$$

$$d = s\sqrt{2} = \frac{p}{4}\sqrt{2} = \sqrt{2a}; s = \frac{d}{\sqrt{2}} = \frac{p}{4} = \sqrt{a}; p = 2d\sqrt{2} = 4s = 4\sqrt{a};$$

$$a = \frac{d^2}{2} = s^2 = \frac{p^2}{16}.$$

(For convenience of calculation: $\pi = 3.141592+$, $\log = 0.4971499$;

$\frac{\pi}{4} = 0.785398+$, $\log = 9.8950899$; $\frac{1}{\pi} = 0.318310-$, $\log = 9.5028501$;

$\log 4 = 0.6020600$; $\log \frac{1}{4} = 9.3979400$; $\log 2 = 0.3010300$;

$\sqrt{2} = 1.414214-$, $\log = 0.1505150$; $\frac{1}{\sqrt{2}} = 0.707107$, $\log = 9.8494850$.)

Fig. 15.

of an inch reduced to decimals, see Table 8, Ele-

11.—CIRCUMFERENCES *C* OF CIRCLES FOR GIVEN—
Circumferences are directly proportional to the diameters.

Diameter may be obtained from circumferences by inverse interpolation.
 Note.—Area of surface of *Sphere* = diameter $\times$ circumference = $D \times C$.
 Values in this table are also multiples of π .

—DIAMETERS D , IN DECIMALS.

This table may be used like logarithmic tables.

Diff. between any two successive circumferences = .0314+; hence, if the diameter is extended to the third decimal place (thousandths), add .00314+ multiplied by the thousandth figure). *Ex.*—*Diam.* = 7.528; then *circum.* = 23.6248+.0094 = 23.6342.

12.—CIRCUMFERENCES OF CIRCLES FOR GIVEN—
Circumferences are directly proportional to the diameters.

Diameters may be obtained from circumferences by inverse interpolation.

Note.—Area of surface of Sphere = diameter X circumference.

The Circumferences are in the same Denomination as that for which the First Column is used. Ex:—Dia. = 14.125 ft. = 14 ft. 1½ ins.: then, Circumference = 44.375 ft.

—DIAMETERS, IN FEET AND INCHES; AND IN INCHES.

This table may be used like logarithmic tables.

Diff. between any two successive circumferences in 12ths = .2618; hence if the diameter is extended beyond 12ths, this diff. must be used proportionately. Diff. between any two successive circumferences in 8ths = .3927; hence, if the diameter is extended beyond 8ths, this diff. must be used proportionately.

The Circumferences are in the same Denomination as that for which the First Column is used.

12.—CIRCUMFERENCES OF CIRCLES FOR GIVEN—
Circumferences are directly proportional to the diameters.

Diameters may be obtained from circumferences by inverse interpolation.

Note.—Area of surface of Sphere = diameter X circumference.

The Circumferences are in the same Denomination as that for which the First Column is used. Ex.—Dia. = 62.25 ins. = 62 $\frac{1}{4}$ ins.: then, Circumference = 195.664 ins.

—DIAMETERS IN FEET AND INCHES; AND IN INCHES.—Concluded.

This table may be used like logarithmic tables.

Diff. between any two successive circumferences in 12ths = .2618; hence, if the diameter is extended beyond 12ths, this *diff.* must be used proportionately. *Diff.* between any two successive circumferences in 8ths = .3927; hence, if the diameter is extended beyond 8ths, this *diff.* must be used proportionately.

The Circumferences are in the same Denomination as that for which the First Column is used.

Note.—Diameters in inches are in heavy type, with fractions of an inch "in column" opposite the areas.

The range of this table may be enlarged by noting that areas of circles are proportional to the squares of their diameters.

Spheres: Surface = $d \times \text{diam.}$ Volume = $\frac{1}{6} d \times \text{diam.}^2 \times \text{diam.}$ (Assuming $d = \text{diam.}$ of circle.)

AMETERS IN INCHES AND FRACTIONS.

Ex.—For dia. of 64 ins., area equals 3217.0 sq. ins. For dia. of 66½ ins., area equals 3460.2 sq. ins.
 Ex.—For dia. of ½ in., area is ¼ of that for 1 in. For dia. of 50½ in., area is ¼ of that for 100½ ins. For dia. of 200½ ins., area is ¼ of that for 100½ ins.

14.—AREAS OF CIRCLES IN SQUARE FEET* FOR GIVEN—

Note.—Diameters in feet are in heavy type, with decimals of a foot "in column" opposite the areas.

* Or any other denomination. Note that areas of circles are proportional to the squares of their diameters, and that the range of the table may therefore be extended greatly.

Spheres: Surface = $4 \times$ above areas. Volume = $\frac{1}{6}$ diam. $\times$ above areas. (Assuming diam. of sphere = diam. of circle.)

DIAMETERS IN FEET* AND TENTHS.

decimal point in the diameter = 2 decimal points
a. of 5.41, area equals 22.987.

denomination. Diameters and areas must be in the same
meters, feet or inches, etc.
Areas of circles are proportional to the squares of their dia-
meters, and the range of the table may therefore be extended greatly.

15.—AREAS OF CIRCLES IN SQUARE FEET FOR GIVEN—

Note.—Diameters in feet are in heavy type, with inches " in column opposite the areas.

Areas of circles are proportional to the squares of their diameters.

Spheres: Surface = 4 × above areas. Volume = $\frac{1}{6}$ diam. × above area (Assuming diam. of sphere = diam. of circle.)

ETERS IN FEET AND INCHES.

of 65 ft., area equals 3318.31 sq. ft.
 of 90' - 6", area equals 6432.61 sq. ft.

Fig. 17.

Segment; Parabolic Half-Segment; and Parabolic
n of Parabola, see page 257.)

Parabola (Fig. 17):

ord; $\frac{h}{c}$ may have any value desired.

$$= 2h \sqrt{\frac{c^2}{16h^2} + 1} + \frac{c^2}{8h} \log^* \frac{4h}{c} \left(1 + \sqrt{\frac{c^2}{16h^2} + 1} \right). \text{ (Exact.)}$$

$$= 2 \sqrt{\frac{c^2}{4} + \frac{1}{2}h^2}. \text{ (Approximate†.)}$$

$$h = \frac{1}{2} \text{ base} \times \text{altitude} = \frac{1}{2} c h.$$

$$\text{ent of height } h' = c \sqrt{\frac{h'}{h}}.$$

$$h' = \frac{1}{2} c' h' = \frac{1}{2} c h' \sqrt{\frac{h'}{h}}.$$

$$= \frac{1}{2} c \left(h - h' \sqrt{\frac{h'}{h}} \right).$$

$$\text{of } AOB = \frac{1}{2} h \times \frac{c}{2} = \frac{1}{4} c h.$$

$$\text{of half segment of height } h = \frac{1}{2} \times \frac{c}{2} = \frac{1}{4} c.$$

$$\text{and } G_1 \text{ of segment and half segment } (h) = \frac{1}{2} h.$$

$$\text{f spandril} = \frac{1}{2} \times \frac{c}{2} = \frac{1}{4} c.$$

$$\text{f spandril} = \frac{1}{10} h.$$

$$\text{at } d; T_1 \text{ is tangent at } A; T_2 \text{ at } p_2.$$

$$\frac{A p_1}{T_1} = \frac{C p}{T} = \frac{02}{c}.$$

atural) log = common (Briggs) log mult by 2.3025851,
is 0.3622157.

lues, mult result from approx formula by 0.99975

0.9972 when $\frac{h}{c} = 0.2$; by 0.99 when $\frac{h}{c} = 0.3$; by

0.923 when $h = c$.

Parabola may be drawn (1) by drawing T_2 in various positions between T and T_1 , varying the distance $A p_1 = C p$ and using the preceding equations for position of p_2 , although the latter is not absolutely necessary.

Parabola may be drawn (2) by the method adopted for the right-hand half of arc a (Fig. 17): dividing the half-chord and the height into equal spaces (any number) and joining points of intersection of verticals with corresponding inclined lines, as 1-5 with $O-a$, 2-6 with $O-b$, etc.

Parabola may be drawn (3) by laying off ordinates from the base. Thus, if base is divided into 8 parts the middle ordinate $= (4)^2 k = k$, in which $k =$ a constant $= \frac{1}{16} k$. Then the ordinates at 0 and 8 are $0 \times 8k$; at 1 and 7 are $1 \times 7k$; at 2 and 6 are $2 \times 6k$; at 3 and 5 are $3 \times 5k$; at 4 is $16k$. It matters not how many divisions of the base are used, whether odd or even. If odd, say 11, the middle ordinate $= (5.5)^2 k$. Also, the ordinate midway between 1 and 2 (Fig. 17) $= 1.5 \times 6.5 k$.

16.—LENGTHS OF PARABOLIC ARCS FOR CHORD (BASE) 1.

Calculated from the exact equation, preceding.

Fig. 18.

Ellipse.—The Ellipse is a flattened circle. (See Analytic Geometry. Fig. 9, page 258.)

Notation and Methods of Drawing the Ellipse (Fig. 18):

$$a = \text{semi-major axis} = \frac{d}{e} = \sqrt{b^2 + d^2} = \frac{1}{2} s = \frac{1}{2} (u + v) = \frac{x}{\sqrt{1 - \frac{y^2}{b^2}}} = \frac{bx}{\sqrt{b^2 - y^2}}$$

$$b = \text{semi-minor axis} = d \sqrt{\frac{1}{e^2} - 1} = \sqrt{a^2 - d^2} = \sqrt{(a + d)(a - d)} = \frac{y}{\sqrt{1 - \frac{x^2}{a^2}}} = \frac{ay}{\sqrt{a^2 - x^2}}$$

$$e = \text{eccentricity of ellipse} = \frac{d}{a} = \sin \beta = \frac{\sqrt{a^2 - b^2}}{a} = \sqrt{1 - \frac{b^2}{a^2}}$$

$$d = \frac{1}{2} (\text{focal distance}) = \sqrt{a^2 - b^2} = \sqrt{(a+b)(a-b)}.$$

$$s (= \text{span}) = \text{major axis} = 2a = u + v = \frac{2d}{e} = 2\sqrt{b^2 + d^2}.$$

$$\left. \begin{aligned} x &= \text{variable abscissa} = a \sqrt{1 - \frac{y^2}{b^2}} \\ y &= \text{variable ordinate} = b \sqrt{1 - \frac{x^2}{a^2}} \end{aligned} \right\} \text{ Sometimes used in platting } (p'') \text{ or laying out the ellipse.}$$

$u + v = a$ constant $= 2a$ (see point p); common method of drawing the ellipse.

$a - b =$ constant distance bet axis on line of "elliptic compass" (see pt. p').

Other Properties of the Ellipse:

Dist x_0 to cen of grav g_1 of quadrant or g of half-ellipse $= 0.42441 a$.

Dist y_0 to cen of grav g_1 of quadrant or G of half-ellipse $= 0.42441 b$.

Dist r_0 to cen of grav g_1 of quadrant $= \sqrt{x_0^2 + y_0^2} = 0.42441 \sqrt{a^2 + b^2}$.

Line n is normal to the ellipse at point p , and bisects angle α .

Line t is tangent to the ellipse at point p , and is at $\perp$ with n .

$$\begin{aligned} \text{Area of ellipse} &= \pi ab = \frac{\pi bd}{e} = \frac{\pi}{2} s b = \frac{\pi}{2} b (u + v). \quad (\pi = 3.1416.) \\ &= 0.7854 \times \text{major axis} \times \text{minor axis.} \end{aligned}$$

FORMULAS FOR CIRCUMFERENCE OR PERIMETER OF ELLIPSE:

Method 1.—Let l = perimeter; s = major axis $= 2a$; e^2 = (eccentricity) $^2 = \frac{d^2}{a^2} = \frac{(a+b)(a-b)}{a^2}$.

$$\text{Then } l = \pi \left[s \left(1 - \frac{1}{2^2} e^2 - \frac{3}{2^2 \cdot 4^2} e^4 - \frac{3^2 \cdot 5}{2^2 \cdot 4^2 \cdot 6^2} e^6 - \frac{3^2 \cdot 5^2 \cdot 7}{2^2 \cdot 4^2 \cdot 6^2 \cdot 8^2} e^8 - \frac{3^2 \cdot 5^2 \cdot 7^2 \cdot 9}{2^2 \cdot 4^2 \cdot 6^2 \cdot 8^2 \cdot 10^2} e^{10} - \frac{3^2 \cdot 5^2 \cdot 7^2 \cdot 9^2 \cdot 11}{2^2 \cdot 4^2 \cdot 6^2 \cdot 8^2 \cdot 10^2 \cdot 12^2} e^{12} - \dots \right) \right] \quad (1)$$

$$\text{Then } l = \pi \left[s \left(1 - \frac{1}{4} e^2 - \frac{3}{64} e^4 - \frac{5}{256} e^6 - \frac{175}{16384} e^8 - \frac{441}{65536} e^{10} - \frac{4851}{1048576} e^{12} - \dots \right) \right] \quad (2)$$

Formulas (1) and (2) may be expressed: $l = \pi[s(k)]$ (3) in which the continued series k is a coefficient of s , making sk the diameter of a circle whose circumference = perimeter of the ellipse.

To facilitate the use of equation (2): $\log \pi = 0.4971499$; $\log \frac{1}{4} = 9.3979400$; $\log \frac{3}{64} = 8.6709413$; $\log \frac{5}{256} = 8.2907300$; $\log \frac{175}{16384} = 8.0286181$; $\log \frac{441}{65536} = 7.8279587$; $\log \frac{4851}{1048576} = 7.6652314$. Note that logarithms of $e^4, e^6, e^8, e^{10}, e^{12}$ are 2, 3, 5, 6 times $\log e^2$.

Problem 1.—The major and minor axes of an ellipse are 36 and 24 ft., respectively. Find the perimeter?

$$\text{Solution.}—\text{Major axis } s = 36; a = 18; b = 12; e^2 = \frac{180}{18^2}; \log e^2 = 9.7447275.$$

Using 5-place logarithms, we have for the value of k , by terms:

1	2	3	4	5	6	7
$\log \frac{1}{4} = 9.39794$	$\frac{3}{64} = 8.67094$	8.29073	8.02862	7.82796	7.66523	
$\log e^2 = 9.74473$	$e^4 = 9.48946$	$e^6 = 9.23418$	$e^8 = 8.97891$	$e^{10} = 8.72364$	$e^{12} = 8.46837$	
Sum	9.14267	8.16040	7.52491	7.00753	6.55160	6.13360

and numbers corresponding to above logarithms are below:

$k = 1.00000 - 0.13889 - 0.01447 - 0.00335 - 0.00102 - 0.00036 - 0.00014$ minus the sum of the value of terms above the 7th, which, by inspection, we will assume to equal 0.00007. Hence, $k = 0.8417$; and the perimeter $l = \pi sk = 3.1416 \times 36 \times 0.8417 = 95.194$ ft. *Ans.*

Method 2.—Let l = perimeter; a = semi-major axis; b = semi-minor axis;

$$E = \frac{a-b}{a+b}.$$

$$\text{Then } l = \pi(a+b) \left[1 + \frac{1}{2^2} E^2 + \frac{1}{2^2 \cdot 4^2} E^4 + \frac{3^2}{2^2 \cdot 4^2 \cdot 6^2} E^6 + \frac{5^2}{2^2 \cdot 4^2 \cdot 6^2 \cdot 8^2} E^8 + \frac{3^2 \cdot 5^2 \cdot 7^2}{2^2 \cdot 4^2 \cdot 6^2 \cdot 8^2 \cdot 10^2} E^{10} + \frac{3^2 \cdot 5^2 \cdot 7^2 \cdot 9^2}{2^2 \cdot 4^2 \cdot 6^2 \cdot 8^2 \cdot 10^2 \cdot 12^2} E^{12} + \dots \right] \quad (4)$$

$$\text{Then } l = \pi(a+b) \left[1 + \frac{E^2}{4} + \frac{E^4}{64} + \frac{E^6}{256} + \frac{5E^8}{16384} + \frac{49E^{10}}{65536} + \frac{441E^{12}}{1048576} + \dots \right] \quad (5)$$

Formulas (4) and (5) may be expressed: $l = \pi(a+b)K$ (6)
in which $(a+b)K$ is the diameter of a circle whose circumference = perimeter of the ellipse.

To facilitate the use of equation (5): $\log \pi = 0.4971499$; $\log \frac{1}{4} = 9.397400$; $\log \frac{1}{64} = 8.193820$; $\log \frac{1}{256} = 7.591760$; $\log \frac{5}{16384} = 7.183520$; $\log \frac{49}{65536} = 6.873716$; $\log \frac{441}{1048576} = 6.623837$. Note that logarithms of $E^2, E^4, E^6, E^8, E^{10}, E^{12}$ are 2, 4, 6, 8, 10, 12 times $\log E$.

Problem 2.—Solve problem 1 by formula (5)?

Solution.— $a = 18$; $b = 12$; $a+b = 30$; $a-b = 6$; $E = 0.2$; $\log E = 9.3010300$. Using 5-place logarithms, we have for the value of K , by terms:

1	2	3	4	5	6	7
$\log \frac{1}{4} = 9.39794$	$\frac{1}{64} = 8.19382$	$\frac{1}{256} = 7.59176$	$\frac{5}{16384} = 7.18352$	$\frac{49}{65536} = 6.87372$	$\frac{441}{1048576} = 6.62384$	
$\log E^2 = 8.60206$	$E^4 = 7.20412$	$E^6 = 5.80618$	$E^8 = 4.40824$	$E^{10} = 3.01030$	$E^{12} = 1.61236$	
Sum = 2.00000	5.39794	7.39794	9.59176	11.88402	12.23620	

and numbers corresponding to above logarithms are below:
 $\therefore K = 1 + 0.010000 + 0.000025 + 0.00000025 + \dots = 1.0100253$; and the perimeter $l = \pi(a+b)K = 95.193$. Ans.

Comparison of Methods 1 and 2.—A mere glance at the solution of Problems 1 and 2, illustrating the two preceding methods of calculating the perimeter of the ellipse, clearly shows the *superiority of Method 2*: The 5th, 6th, 7th, etc., terms giving values so small as to be negligible in the present instance. Moreover, equation (5), with the accompanying logarithmic values given just below it, will be found quite as rapid to use, in many cases, as many of our so-called approximate formulas, with, in addition, the advantage of accuracy.

17.—LENGTHS OF SEMI-ELLIPTIC ARCS, A OR B
 FOR a =UNITY, AND FOR SUCCESSIVE VALUES OF $\frac{b}{a}$.

Note.—To find A or B : Multiply values of coefficient C , in the table, by length of semi-major axis, or a . Thus, $A = B = Ca$.

[Calculated from Formula (4-5).*]

Elliptic Segment; and Chord.—

Let A = areas of elliptic segment with chord

C_a ;
 B = area of elliptic segment with chord

C_b ;

a = semi-major axis = rad of large circle;

b = semi-minor axis = rad of small circle;

$b - b'$ = rise of segment A ;

$a - a'$ = rise of segment B .

Then, length of chord $C_a = 2a\sqrt{1 - \left(\frac{b'}{b}\right)^2}$;

length of chord $C_b = 2b\sqrt{1 - \left(\frac{a'}{a}\right)^2}$.

Fig. 10.

Area segment A : area whole ellipse :: area seg small circle : area small circle.

$$\therefore A = (\text{area seg small circle with same chord } C_a) \times \frac{a}{b} \dots (1)$$

Area segment B : area whole ellipse :: area seg large circle : area large circle,

$$\therefore B = (\text{area seg large circle with same chord } C_b) \times \frac{b}{a} \dots (2)$$

(See Tables 7 and 8 of Circular Segments, preceding.)

Problem 1.—Find the area of segment A of the ellipse $a = 10$, $b = 8$, whose chord is distant $b' = 5$ from and parallel with the major axis?

Solution.—Diam of small circle = 16, and middle rise h ($= b - b'$) of arc from chord = $8 - 5 = 3$. Now from Table 8, of Circular Segments, the area corresponding to $\frac{\text{rise } 3}{\text{diam } 16}$, or .1875, = .10193 diam² = .10193 $\times 4b^2$; and

multiplying this value by $\frac{a}{b}$ (see Equation 1) we have,

$$\text{Area } A = .10193 \times 4ab = .10193 \times 320 = 32.622. \text{ Ans.}$$

It is to be noted that area A = area B when $\frac{b'}{b} = \frac{a'}{a}$.

Problem 2.—What is the length of chord C_a of the ellipse given in Problem 1?

Solution.—From the above formula, $C_a = 2a\sqrt{1 - \left(\frac{b'}{b}\right)^2} = 20\sqrt{1 - \frac{25}{64}} = 15.612. \text{ Ans.}$

B.—SOLIDS.

Pappus's Theorem.—If a plane curve l or area a lies wholly on one side of a straight line as axis in its own plane, the surface S or volume V generated by its whole or partial revolution about that axis is:

$S = l \times$ length of path p traversed by cen of grav g of line; or $S = lp$;
 $V = a \times$ length of path P traversed by cen of grav G of area; or $V = aP$.

If x_0 = distance from axis to g } then for one complete revolution,
 X_0 = distance from axis to G }

$p = 2\pi x_0$; $\therefore S = 2\pi l x_0$, and $x_0 = S + 2\pi l$ (1)

$P = 2\pi X_0$; $\therefore V = 2\pi a X_0$, and $X_0 = V + 2\pi a$ (2)

Thus, equations (1) and (2) are used for finding the surfaces and volumes of the sphere, cone, cylinder, torus (cylindrical ring), paraboloid, ellipsoid, etc.; also of their sectors, segments, zones and frustums.

It is to be noted also that these equations enable us to find the centers of gravity of their lines and areas when their lines, surfaces and volumes are known.

Prismoidal Formula.—The volume V of a prismoid is equal to the length l multiplied by the mean area A ; and A is equal to $\frac{1}{3}$ (sum of end areas, a_1 and a_2 , + 4 times the middle area a_m); thus

$$V = lA = \frac{l}{6} (a_1 + 4a_m + a_2) \dots\dots\dots (3)$$

A prismoid is a solid having *parallel* end faces or areas, joined together by *regular* surfaces or sides, as the sides of prisms, cylinders, cones, pyramids, wedges, or their frustums, or any lateral combination of same. The prismoidal formula will apply also to the sphere, hemisphere and spherical segment; to warped-surface solids where the warp is continuous between ends of solid; to railroad cuttings that can be decomposed into prisms, wedges, etc.; to two equal cones arranged like an hour glass with bases as end areas; to the conical wedge bounded on one side by a plane radiating from the apex of cone; to the frustums of same; and to many other solids.

18.—THE FIVE REGULAR POLYHEDRONS.

(All dihedral or solid angles are equal, and all faces regular polygons. Five only.)

NAME.	Bounded by	Total Surface S = (1 edge) ² times	Total Volume V = (1 edge) ³ times	Apothem a , or radius of inscribed sphere, = 1 edge times	Radius r , or radius of circum- scribed sphere, = 1 edge times
Tetrahedron.....	4 $\triangle$'s	1.7320508	0.1178513	0.2041	0.6124
Cube (hexahedron)	6 $\square$'s	6.0000000	1.0000000	0.5000	0.8660
Octahedron.....	8 $\triangle$'s	3.4641016	0.4714045	0.4082	0.7071
Dodecahedron....	12 $\square$'s	20.6457788	7.6631189	1.1136	1.4013
Icosahedron.....	20 $\triangle$'s	8.6602540	2.1816950	0.7558	0.9511

The volume V of any regular polyhedron is equal to its surface S times one-third its apothem a ; or, $V = \frac{1}{3} Sa$; $\therefore a = 3V + S$.

Fig. 20.

Prisms and Cylinders.—A *prism* is a solid with *parallel ends* and *parallel side edges*. Hence the ends will be equal and similar polygons (regular or irregular), and the sides will be parallelograms. A *cylinder* is a prism with an infinite number of sides. The ends of the cylinder may be circular, elliptic, or of any curvature.

Area.—The surface of any prism or cylinder, whether right or oblique, is equal to the two end areas + the perimeter p of any right section s multiplied by the length l of any lateral element; or $S = 2a + pl$ (Fig. 20).

Volume.—The volume of any prism or cylinder, whether right or oblique, is equal to the area of any right section s multiplied by the length l of any lateral element; or $V = sl$ (Fig. 20).

Also, volume equals area of either end multiplied by the vertical distance between the end faces; or, $V = ah$ (Fig. 20).

Frustum of Prism or Cylinder.—Prism or cylinder with end faces not parallel (Fig. 21).

Volume.—Let $g_1 = \text{cen of grav of end area } a_1$; g_2 of any sectional area a_2 ; g_3 of end area a_3 . Then

$V = a_1 h_1$; ($h_1 = \text{vert dist from } g_3 \text{ to plane } a_1$).

$V = a_3 h_3$; ($h_3 = \text{vert dist from } g_1 \text{ to plane } a_3$).

$V = a_2 h_2$; (h_2 is vert to plane a_2 , bet g_1 and g_3 .)

In general, $V = \text{area } a$ of any plane section multiplied by the perpendicular distance h between planes passing through centers of gravity of end areas and parallel with the said plane section. If a is a right section a_0 , $V = a_0 l$. These formulas also enable us to find the relation between certain elements, as $a_0 l = a_1 h_1 = a_2 h_2 = a_3 h_3$.

Note that Fig. 21 becomes a *circular cylindric ungula* when the right section a_0 is a circle, and hence $l = \frac{1}{2}(l_1 + l_2)$ (longest side + shortest side).

Fig. 21.

Circular Cylindric Frustum.—This is a special case of the preceding in which a_0 is a right circular section whose perimeter is p . Then,

Volume $V = a_0 l = \frac{1}{2} a_0 (l_1 + l_2)$;

$V = a_1 h_1$; (h_1 is *perp* to plane a_1 .)

$V = a_3 h_3$; (h_3 is *perp* to plane a_3 .)

Area $A = a_1 + a_3 + pl = a_1 + a_3 + p(l_1 + l_2)$.

Fig. 22.

Fig. 23b.

Fig. 23c.

Fig. 23d.

Half-Wedges. — The following formulas give the half-wedges cut from circular cylinders; h being the height measured along the element of the cylinder at a_1 , (b), (c) and (d)—as follows:—

less than radius r ; lower edge c_1 .

Area of base at b_1 $(r - b_1)$]. (Fig. 23a)

$S = \frac{h}{b_1} [c_1 r - (\text{length of arc } a_1) (r - b_1)]$. (Fig. 23a)

radius of cylinder; lower edge $= d$.

(Fig. 23b)

$S = 2rh = dh$.

(Fig. 23b)

$> r$ and $<$ diameter d ; lower edge $= c_2$.

Area of base at b_2 $(b_2 - r)$]. (Fig. 23c)

$S = \frac{h}{b_2} [c_2 r + (2\pi r - \text{arc } a_2) (b_2 - r)]$. (Fig. 23c)

diameter of cylinder; lower edge at a_2 .

(area of circular base). (Fig. 23d)

$S = \pi rh$. (Fig. 23d)

Whether figure is right or oblique. (Fig. 23d)

For right or oblique figure, h being *perp* height.

Surface, for right figure only. For total surface, add base (circular).

19.—PROPERTIES OF HOLLOW CYLINDERS (PIPES, TANKS OR WELLS), ONE FOOT IN LENGTH.

Note that Areas, Volumes, Capacities and Weights are proportional to the squares of the diameters. 1728 cu. ins. = 7.4805 gallons = 1 cu. ft. = 62.5 lbs. (nearly) of water; 231 cu. ins. = 1 gallon; 201.974 gallons = 1 cu. yd.

Pyramid and Pyramidal Frustum.—A "regular" pyramid is one in which the base is a regular polygon; if not, it is "irregular." If the axis, from the *apex* to the cen of grav g of the base, is perp to the base it is a "right" pyramid; if not, it is "oblique." Fig. 24 shows an oblique pyramid and frustum together forming a right pyramid.

Volume V_r of right pyramid = $\frac{1}{3}$ (area of base $\times$ perp height) = $\frac{1}{3} a_1 h_1$.

Volume V_o of oblique pyramid = $\frac{1}{3}$ (area of base $\times$ perp height) = $\frac{1}{3} a_2 h_2$.

Volume V_f of pyramidal frustum = $V_r - V_o = \frac{1}{3} (a_1 h_1 - a_2 h_2)$.

Fig. 24.

If a_2 is parallel with a_1 , applying the prismoidal formula, volume V_f of frustum = $\frac{h_1 - h_2}{3} (a_1 + a_2 + \sqrt{a_1 a_2})$, whether pyramid is right or oblique, regular or irregular.

The area of the sides of a right regular pyramid = $\frac{1}{2}$ (perimeter of base $\times$ least slant height); of a right regular frustum with parallel faces = $\frac{1}{2}$ (perimeter of top + perimeter of base) $\times$ least slant height.

For area of an oblique or irregular pyramid or frustum, the sides must be calculated—as triangles, or as trapezoids or trapeziums, respectively. No simple general formula will apply.

Center of gravity of pyramid, whether right or oblique, lies in the axis, and one-fourth its length from the base.

Cone and Conic Frustum.—A cone may be considered as a pyramid with an infinite number of sides. If the axis from the *apex* to the cen of grav g of the base, is perp to the base it is a "right" cone; if not, it is "oblique." Generally speaking, a right cone is understood to have a circular base; and an oblique cone, to have an elliptic base. Such cones, however, are sometimes termed right- and oblique circular cones, to distinguish them from right- and oblique elliptic cones whose base of right cone is an ellipse. Note that an oblique circular cone may be cut from a right elliptic cone; or that an oblique elliptic cone may be cut from either a circular or an elliptic cone. Fig. 25 shows an oblique cone and frustum together forming a right cone.

Fig. 25.

Volume V_r of right cone = $\frac{1}{3}$ (area of base $\times$ perp height) = $\frac{1}{3} a_1 h_1$.

Volume V_o of oblique cone = $\frac{1}{3}$ (area of base $\times$ perp height) = $\frac{1}{3} a_2 h_2$.

Volume V_f of conic frustum = $V_r - V_o = \frac{1}{3} (a_1 h_1 - a_2 h_2)$.

If a_2 is parallel with a_1 , applying the prismoidal formula, volume V_f of frustum = $\frac{h_1 - h_2}{3} (a_1 + a_2 + \sqrt{a_1 a_2})$.*

The area of the curved surface (side) of a right cone = $\frac{1}{2}$ (perim of base $\times$ slant height); of a right frustum with parallel faces = $\frac{1}{2}$ (perim of top + perim of base) $\times$ slant height.

* If the bottom and top faces of the frustum are circles with radii r_1 and r_2 , respectively, then $a_1 = \pi r_1^2$ and $a_2 = \pi r_2^2$. If they are elliptical, use the formula: area of ellipse = πab , in which a = semi-major axis and b = semi-minor axis. $\pi = 3.1416$.

The area of the curved surface (side) of an *oblique elliptic cone* of height h_2 (Fig. 25), and which has been cut from a *right circular cone*, $= \frac{a_2 h_2}{r'}$, in which h_2 = perp height, a_2 = area of elliptic base, and $r' = h_2 \frac{\sin \beta}{\cos \alpha}$ = perp dist from side of right circular cone to point where axis of same pierces base a_2 of oblique cone. Hence, area $= \frac{a_2 h_2}{r'} = \frac{a_2 \cos \alpha}{\sin \beta}$. Also, area $= \frac{3}{r'} (\text{volume of oblique cone}) = \frac{3V_o}{r'}$.

Center of gravity of cone, whether right or oblique, lies in the axis and one-fourth its length from the base.

Conic Wedge and Frustum from right cone.—If the wedge is cut from the cone by a plane passing through the apex (Fig. 26), with a_2 parallel to a_1 , we have,

$$\begin{aligned} V_1 &= \frac{1}{3} a_1 h_1; A_1 = \frac{1}{2} h_1 p_1. \quad (p_1 = \text{perim of } a_1.) \\ V_2 &= \frac{1}{3} a_2 h_2; A_2 = \frac{1}{2} h_2 p_2. \quad (p_2 = \text{perim of } a_2.) \\ \text{Volume of frustum} &= V_1 - V_2 = \frac{1}{3} (a_1 h_1 - a_2 h_2). \\ \text{Area of frustum} &= A_1 - A_2 = \frac{1}{2} (h_1 p_1 - h_2 p_2); \\ &\quad (\text{ends not included}). \end{aligned}$$

Volume of frustum may also be derived from the prismoidal formula;

$$\begin{aligned} \text{thus, } V_f &= \frac{h_1 - h_2}{6} (a_1 + a_2 + 4a_m) \text{ in which } a_m, \text{ the area of the middle section,} \\ &= \frac{1}{4} \sqrt{a_1 a_2} + \frac{1}{4} (a_1 + a_2); \text{ or, } V_f = \frac{h_1 - h_2}{3} \left(a_1 + a_2 + \sqrt{a_1 a_2} \right). \end{aligned}$$

Note.—The above formulas for *volume*, V_1 , V_2 and V_f , will apply also if the cone is oblique. For an oblique circular cone the above formulas for *area* will not apply; but see formulas for area of oblique elliptic cone above.

Wedge.—In Fig. 27 let w = width, and l = length of base, which must be a parallelogram but not necessarily a rectangle; let h be the perp height of cutting edge above the base; and e the length of cutting edge, which must be parallel with l . Then volume $V = \frac{wh}{6} (2l + e)$. The two ends and two faces of height h may slope in any direction; the two ends need not be parallel.

Fig. 26.

Fig. 27.

Sphere.—A sphere is generated by the complete revolution of a semi-circle (Fig. 28) about its diameter. The *volume* of the sphere is equal to the area of the semicircle $\times$ the path described by its center of gravity G ; the *area of the surface* of the sphere is equal to the length of semi-circular arc $\times$ the path described by its center of gravity g . Any section of a sphere cut by a plane is a circle; and if the plane cuts the center, it is a great circle. The axis of a sphere always lies in the plane of a great circle. The ratio of volume to surface of a sphere is greater than that of any other solid.

Fig. 28.

<i>Distance Y. to G of semi-circle (area)</i>	$= \frac{1}{2} \cdot \frac{r}{\pi} = 0.42441\ 31816\ r.$
<i>Distance y. to g of semi-circular arc</i>	$= \frac{2r}{\pi} = 0.63661\ 97724\ r.$
<i>Area of semicircle</i>	$= \frac{\pi r^2}{2} = 1.57079\ 63268\ r^2.$
<i>Length of semi-circular arc</i>	$= \pi r = 3.14159\ 26536\ r.$

The following are some of the relations of Volume, Surface, Area of Great Circle, Circumference, Diameter and Radius, of the sphere:

$$\text{Volume of Sphere} = \frac{4}{3}\pi \text{ radius}^3 = 4.18879 \text{ radius}^3 = \frac{\pi}{6} \text{ diam}^3$$

$$= 0.52360 \text{ diam}^3 = \frac{1}{6\pi^2} \text{ circum}^3 = 0.016887 \text{ circum}^3$$

$$= \frac{1}{2} \text{ radius} \times \text{area great circle} = \frac{1}{2} \text{ diam} \times \text{area great circle}$$

$$= \frac{1}{2} \text{ radius} \times \text{surface of sphere} = \frac{1}{2} \text{ diam} \times \text{surface of sphere}$$

$$= \frac{\pi\sqrt{3}}{2} (= 2.161128) \text{ volume of inscribed cube}^*$$

$$= \frac{\pi}{6} (= 0.52360) \text{ volume of circumscribing cube}$$

$$= \sqrt{3} (= 1.732051) \text{ volume of maximum inscribed cylinder}^\dagger$$

$$= \frac{1}{2} \text{ volume of circumscribing cylinder.}$$

Volumes of spheres are as the *cubes* of their radii or their diameters.

$$\text{Surface of Sphere} = 4\pi \text{ radius}^2 = 12.56637 \text{ radius}^2 = \pi \text{ diam}^2$$

$$= 3.14159 \text{ diam}^2 = \frac{1}{\pi} \text{ circum}^2 = 0.31831 \text{ circum}^2 = \text{diam} \times \text{circum}$$

$$= 4 \times \text{area great circle} = \text{area of circle whose radius is equal to diam of sphere} = 3 \times \text{volume} + \text{radius of sphere.}$$

$$= \frac{\pi}{2} (= 1.57080) \text{ area of surface of inscribed cube}$$

$$= \frac{\pi}{6} (= 0.52360) \text{ area of surface of circumscribing cube}$$

$$= 4 \times \text{area of convex surface of inscribed cylinder of max convex surface}^\ddagger$$

$$= \text{convex surface of circumscribing cylinder}$$

$$= 3\sqrt{3} (= 5.19615) \text{ convex surface of inscribed cone of max convex surface}^\S.$$

Surfaces of spheres are as the *squares* of their radii or their diameters.

$$\text{Area of Great Circle of Sphere} = \pi \text{ radius}^2 = 3.141593 \text{ radius}^2 = \frac{\pi}{4} \text{ diam}^2 =$$

$$0.785398 \text{ diam}^2 = \frac{r}{2} \text{ circum of sphere} = \frac{1}{2} \text{ area of surface of sphere} = \frac{1}{2} \text{ volume of sphere} + \text{diam.}$$

$$^* \text{ Edge of inscribed cube} = \frac{1}{\sqrt{3}} (= 0.57735) \text{ diam of sphere.}$$

$$^\dagger \text{ Altitude of inscribed cylinder} = \frac{1}{2}\sqrt{3} (= 1.15470) \text{ rad of sphere;}$$

$$\text{Diam of base of inscribed cylinder} = 2\sqrt{\frac{1}{3}} (= 1.63299) \text{ rad of sphere.}$$

$$^\ddagger \text{ Altitude of inscribed cylinder} = \text{diam of base} = \sqrt{2} \text{ radius of sphere.}$$

$$^\S \text{ Height of inscribed cone} = \frac{1}{2} \text{ diam of sphere; diam of base of inscribed cone} = \frac{1}{2}\sqrt{2} (= 0.4714) \text{ diam of sphere.}$$

Circumference of Sphere = 2π radius = 6.283185 radius = π diam = 3.141593
 diam = (area of surface of sphere) $\div$ diam = $\sqrt{\pi}$ surface of sphere =

$3\frac{1}{4}$	0.268 0826	9.428 2686	$3\frac{1}{4}$ - $3\frac{1}{2}$	0.220 8932	9.344 1824
$3\frac{1}{2}$	0.381 7017	9.581 7241	$3\frac{1}{2}$ - $3\frac{3}{4}$	0.303 0085	9.481 4549
$3\frac{3}{4}$	0.523 5988	9.718 9986	$3\frac{3}{4}$ - 4	0.403 3044	9.605 6330

Ex.—Volume of sphere $\frac{1}{16}$ in. in diam = $0.0_6199737$ cu. in.; therefore, volume of sphere $\frac{1}{4}$ in. in diam = $0.0_6199737 \times 5^3 = 0.00024967$ cu. in.

Ex.—Volume of sphere 7 units in diameter = $0.1795944 \times 10^3 = 179.5944$.

Ex.—Volume of sphere $\frac{1}{8}$ in. in diam = $0.0_65918136$ cu. ft.; therefore, volume of sphere $\frac{1}{4}$ ins. in diam = $0.0_65918136 \times 5^3 = 0.0739767$ cu. ft.

Ex.—Volume of sphere 11 ins. in diameter = 0.4033044 cu. ft.

Remarks.—For Volumes of spheres of various diameters, see—

- Foot note to Table 13, of Circles, with diameters in inches and fractions
- Foot-note to Table 14, of Circles, with diameters in decimals.
- Foot-note to Table 15, of Circles, with diameters in feet and inches.

Fig. 29.

Spherical Segment.—

Let a = area of base of segment = πr^2 ;

A = area of great circle = πR^2 ;

h = height of segment.

Then $r = R \sin \theta$; $h = R \cos \theta$ vers $\theta = r \tan \frac{1}{2} \theta$.

$$\text{Volume of segment} = \frac{h}{2} \left(a + \frac{\pi h^2}{3} \right) = \frac{\pi h}{6} (3r^2 + h^2) = 0.52360 h (3r^2 + h^2)$$

$$= \pi h^2 \left(R - \frac{h}{3} \right) = 3.14159 h^2 \left(R - \frac{h}{3} \right).$$

Convex Surface of segment = $2\pi R h = \frac{3h}{2R^2}$ volume of sphere = $\frac{h}{2R}$ surface

of sphere = $\frac{2h}{R}$ area great circle = $\frac{2hA}{R} = h \times \text{circumference of great circle}.$

It is thus seen that area of convex surface is directly proportional to height h of segment. Hence, from Table of Spheres find the total surface of the sphere for diam = $2R$, and multiply this result by $\frac{h}{2R}$; or, better, from Table 11 or 12, of Circles, multiply the circumference of its great circle by h .

Area of Base of segment = πr^2 .

Spherical Zone.—Volume of zone = volume of sphere minus volume of segments (see Spherical Segment, page 252) = $\frac{\pi}{2} H \left(\frac{H^2}{3} + r_1^2 + r_2^2 \right) = 1.570796 H \left(\frac{H^2}{3} + r_1^2 + r_2^2 \right)$.

Convex Surface of zone = surface of sphere minus convex surface of segments (see Spherical Segment, page 252) = $2\pi RH = H \times$ circum of great circle.

Areas of Bases = πr_1^2 and πr_2^2 .

Hollow Sphere.—Let R = radius to outside surface, and r = radius to inside surface. Then,

Volume = $\frac{4}{3} \pi (R^3 - r^3) = 4.18879 (R^3 - r^3)$. May also be taken from Table of Spheres, by deducting volume of the lesser from volume of greater sphere.

Surface = convex surface + concave surface = $4\pi (R^2 + r^2) = 12.56637$ times $(R^2 + r^2)$. May also be taken from Table of Spheres, by adding together the surfaces of the larger and the smaller spheres.

Circular Segmental Ring.—Let g be the cen of grav of area A of segmental section, with o' as a center, forming a ring about the axis $X-X$. Also let $y_0 + d$ = radial distance from said axis to center of grav g of segment. Then,

Volume of ring = $2\pi A (y_0 + d)$. For values of y_0 and A see Fig. 11, also Tables 7 and 8 of Circular Segments.

Note that when $d=0$, Fig. 31 will represent a sphere with a hollow cylindrical core, points o' and o'' being identical with o . The above formula holds true for any section A , provided that $y_0 + d$ = dist to cen of grav g .

Convex Surface of ring = $2\pi a (Y_0 + d)$, in which a = length of circular arc, and $Y_0 + d$ = dist to cen of grav of arc. (See Fig. 9; also Tables 2, 3 and 4, of Circular Arcs.)

Concave Surface of ring = $2\pi rc$, in which c = chord of arc = width of ring. (See Fig. 9; also Tables 2 and 3 of Circular Arcs.)

Regular Circular Ring.—For any circular ring where section $s-s$ is a regular polygon, circle, ellipse, etc., so that center of grav of area A and of perimeter P of section lies midway between outer and inner circumferences Fig. 32, we have,

Volume of ring = $\frac{\pi}{2} (D + d) \times$ area A of section $s-s$.

Surface of ring = $\frac{\pi}{2} (D + d) \times$ perimeter P of section $s-s$.

Circular Spindle—Generated by revolving circular arc a or segment A about an axis, as $X-X$.

Volume = $3.14159 \left[\frac{c^3}{6} - A \left(\frac{c^2}{4h} - h \right) \right]$
 $= 3.14159 \left(\frac{c^3}{6} - 2Ad \right)$.

Surface = $3.14159 \left[h(a+c) - \frac{c^2}{4h}(a-c) \right]$
 $= 6.283185(cr - ad) = 2\pi(cr - ad)$.

Fig. 30.

Fig. 31.

Fig. 32.

Fig. 33.

Middle Zone (and Frustum) of circular spindle.—Let s (Fig. 33) be height of middle zone; then, if A_z = area of zone of segment,

$$\text{Volume} = 3.14159 \left[\frac{s}{4} \left(c^2 - \frac{s^2}{3} \right) - 2A_z d \right].$$

Convex Surface = $6.283185 \times$ length of "zone-arc" a , $\times$ dist from axis $X-X$ to cen of grav of a .

Segment of circular spindle.—Let s (Fig. 33) be height of segment; then, $\text{Volume} = \frac{1}{2}$ (vol of spindle minus volume of middle frustum).

Convex Surface = $\frac{1}{2}$ (surf of spindle minus convex surface of middle zone).

Parabolic Spindle.—Generated by revolving parabolic arc a (assume same Fig. 33) or segment A , about axis $X-X$.

$\text{Volume} = \frac{1}{8} \pi c h^2 = 1.675516 c h^2 = \frac{1}{8}$ volume of circumscribing cylinder.

Convex Surface = $6.283185 \times$ length of arc $a \times$ dist from axis $X-X$ to cen of grav of arc.

Middle Zone (and Frustum) of parabolic spindle.—Let s (Fig. 33) be height of middle zone, assuming arc a to be parabolic. Then, as $\frac{\pi}{15} = 0.209440$,

$$\text{Volume} = 0.209440 s [8h^2 + 3s^2 + 4hs]. \text{ Note that } s = h \left(1 - \frac{s}{c} \right).$$

(The above formula may be used in determining the contents of casks whose staves are parabolic.)

Convex Surface = $6.283185 \times$ length of "zone-arc" a , $\times$ dist from axis $X-X$ to cen of grav of a .

Segment of parabolic spindle.—Let s (Fig. 33) be height of segment; then, $\text{Volume} = \frac{1}{2}$ (volume of spindle minus volume of middle frustum).

Convex Surface = $\frac{1}{2}$ (surface of spindle minus convex surface of middle zone).

Cycloidal Spindle.—Generated by revolving cycloidal arc a (assume same Fig. 33) or segment A about axis $X-X$.

$$\begin{aligned} \text{Volume} &= \frac{1}{8} \pi^2 h^2 = 6.16850 h^2 = \frac{5}{16\pi} c^2 = 0.198944 c^2 = \frac{5\pi^2}{512} a^2 = 0.09638 a^2 - \\ &\frac{1}{8} \pi c h^2 = 1.96350 c h^2 = \frac{5}{8} \text{ volume of circumscribing cylinder. Note that} \\ h &= \frac{c}{\pi} = \frac{a}{4}. \end{aligned}$$

$$\begin{aligned} \text{Convex Surface} &= \frac{16\pi}{3} h^2 = 16.75516 h^2 = \frac{16}{3\pi} c^2 = 1.69765 c^2 = \frac{\pi}{3} a^2 = 1.04720 a^2 \\ &- \frac{16}{3} c h. \end{aligned}$$

Paraboloid or Parabolic Conoid.—Generated by revolving one-half parabola of arc a , height h , base c , and area A (Fig. 34), about its vertical axis $Y-Y$.

$$\text{Volume} = \frac{\pi}{8} c^2 h = 0.39270 c^2 h = \text{area of base} \times \text{half the height.}$$

$$\text{Volume of parabolic segment of height } h' = \frac{\pi}{8} c^2 h'.$$

$$\text{Volume of parabolic frustum of height } h'' = \frac{\pi}{8} (c^2 h - c^2 h'). \text{ Note that } c' = c \sqrt{\frac{h'}{h}}.$$

12.—ANALYTIC GEOMETRY.

(See also Mensuration.)

Analytic Geometry treats of the algebraic analysis of geometrical figures.

Plane Analytic Geometry, including what is commonly termed Conic Sections or sections cut from cones, deals with the analysis of plane curves referred to two coordinate axes, X and Y . The coordinate distances to any point p (Fig. 1) of the figure are x and y ; x being measured from Y parallel to X , and y being measured from X parallel to Y . One, usually x , is called the *abscissa*, and the other, usually y , is called the *ordinate*, to the point p . They are dependent variables for any particular figure. The coordinate axes, X and Y , lie in the plane of the figure, and their point of intersection is called the *origin*. If the axes are at right angle with each other they are called "rectangular coordinate axes," and the variables x and y are called "rectangular coordinates." This is the usual method.

Solid Analytic Geometry deals with the analysis of solid figures and is therefore sometimes termed Analytic Geometry of Space. Three coordinate axes are used, namely, X , Y and Z , intersecting at the origin; and any point in space may be located by the three coordinates x , y and z , measured parallel to the respective axes.

Straight Line.—Equation: $y = mx + b$.

X and Y are coordinate axes.

x = *abscissa*, measured from axis Y to any point p .

y = *ordinate*, measured from axis X to any point p .

m = tangent of angle of inclination = $\frac{y-b}{x}$.

b = a constant = distance on axis Y from the origin O to the straight line.

Note.—For any point p in 1st quadrant, x and y are plus; 2nd quadrant x is $-$, y is $+$; 3rd quadrant, x and y are minus; 4th quadrant, x is $+$ and y is $-$. For angle upward to the right, m is $+$; downward to the right m is $-$. Straight line cuts Y , *above* origin O when b is $+$; *below*, when b is $-$.

Problem. 1.—A straight line cuts the axis of Y 10 feet above the origin and makes an angle of $(+)$ $6^{\circ}-10'$ with the axis of X . Solve?

Solution.—Natural tang of $6^{\circ}-10' = .108$; $b = 10$; hence the equation $y = .108x + 10$ from which the value of y may be obtained for any value of x , or vice versa. Thus, if $x = 0$, $y = 10$; $x = 1$, $y = 10.108$; $y = 0$, $x = -\frac{10}{.108} = -92.6$; etc.

Problem 2.—Find the point of intersection of the two following lines and plot them: $y = -\frac{1}{2}x + 2$, and $y = x - 8$.

Solution.—Equations:
(1) $y = -\frac{1}{2}x + 2$
(2) $y = x - 8$
diff. $0 = -1\frac{1}{2}x + 10$
 $\therefore \frac{3}{2}x = 10$
 $\therefore x = 6\frac{2}{3}$

Substituting value of $x = 6\frac{2}{3}$ in either of the above equations, we obtain $y = -1\frac{1}{3}$.

$\therefore$ the coordinates of the point p at intersection of the two lines are

$x = +6\frac{2}{3}$, and $y = -1\frac{1}{3}$.

This is also a graphical illustration of Simultaneous Equations, page 103.

Fig. 1.

Fig. 2.

Circle.—Origin at center of circle. Equation of circle: $r^2 = x^2 + y^2$,

whence $r = \pm \sqrt{x^2 + y^2}$; $x = \pm \sqrt{r^2 - y^2}$; $y = \pm \sqrt{r^2 - x^2}$.

Problem.—A circle of 10 ft. radius is cut by a vertical line 8 ft. to the right of its center at the points p and p_1 . What is the length of the chord pp_1 ?

Solution.— $y = \pm \sqrt{r^2 - x^2} = \pm \sqrt{100 - 64} = \pm \sqrt{36} = \pm 6$. Hence, for p , $y = +6$, and for p_1 , $y = -6$.
 $\therefore$ the length of chord = 12 ft.

Fig. 3.

Intersection of circle with an oblique straight line.
Problem.—At what point in the above circle will the straight line $y = 2x - 10$ intersect?

Solution.—Equating the value of y^2 for the circle and for the straight line, $y^2 = r^2 - x^2 = (2x - 10)^2$, we have, eliminating y and making $r^2 = 100$,

$$100 - x^2 = 4x^2 - 40x + 100$$

$$\text{whence } 5x^2 = 40x$$

$$\therefore x = 8, \text{ or } 0;$$

and substituting these values of x in the above equation of the straight line, we have, for $x = 8$, $y = 6$; for $x = 0$, $y = -10$. Hence the line intersects the circle at a point $x = 8$, $y = 6$; which is the same point as p in the above figure. It also intercepts the axis of X at a point $x = 5$; and the axis of Y at a point $y = -10$, at which point it also cuts the lowest point of the circle.

Equation of Tangent to the circle: $x_1x + y_1y = r^2$.
Problem.—The equation of a circle (Fig. 4) is $x^2 + y^2 = 100$. Find the equation of the tangent to the circle at point p , whose abscissa x is 8?

Solution.—Substituting the value of $x (= 8)$ in the equation of the circle, we have

$$y = +\sqrt{100 - 64} = +6, \text{ plus, since } p \text{ is above the axis of } X;$$

and substituting these values of $x = 8$ and $y = 6$ in the above equation of the tangent, and remembering that they correspond with x_1 and y_1 of that equation, we have, for equation of tangent, $8x + 6y = 100$. This tangent cuts the axis of X at $x = 12\frac{1}{2}$, and the axis of Y at $y = 16\frac{2}{3}$ (by making $y = 0$ in the first case and $x = 0$ in the second).

Equation of Normal to the circle: $y_1x - x_1y = 0$. Let it be required to find the normal to the circle (Fig. 4) whose equation is $x^2 + y^2 = 100$. Proceeding as in the above solution for the tangent, we obtain for the normal, $6x - 8y = 0$; or, $y = \frac{3}{4}x$. Clearly, this passes through the origin, at O , for when $x = 0$, $y = 0$.

Fig. 4.

Origin not at center of circle. Equation: $r^2 = (x-a)^2 + (y-b)^2$, whence $r = \pm \sqrt{(x-a)^2 + (y-b)^2}$;
 $x = a \pm \sqrt{r^2 - (y-b)^2}$; $y = b \pm \sqrt{r^2 - (x-a)^2}$.

Equation of above circle may be reduced to $x^2 + y^2 - 2ax - 2by + a^2 + b^2 - r^2 = 0$; or letting $-2a = H$, $-2b = J$, and $a^2 + b^2 - r^2 = K$, we have, $x^2 + y^2 + Hx + Jy + K = 0$.

Equation of tangent to circle:

$$x_1x + y_1y + \frac{H}{2}(x+x_1) + \frac{J}{2}(y+y_1) + K = 0.$$

Parabola.—Next to the circle this is the most useful curve. (See, also, Mensuration, page 237.)

Equation: $y^2 = nx$ (n may be any quantity),
 whence $y = \pm \sqrt{nx}$; $n = \frac{y^2}{x}$; $x = \frac{y^2}{n}$.

The latus rectum (LL) = $2y$ at a point where $y = 2x$. To find this point—

$$y = 2x = \sqrt{nx}$$

$$\therefore 4x^2 = nx$$

$$\therefore x = \frac{n}{4}; \text{ and } n = 4x = 2y =$$

length of latus rectum..

Fig. 5.

Fig. 6.

The *focus* (F) is at the intersection of the latus rectum with the axis X , a distance of $x = \frac{n}{4}$ from the origin, O .

The *directrix* is a line parallel with the axis of Y and distant $\frac{n}{4}$ (the focal distance) to the left of it, so that the axis of Y lies midway between the directrix and the latus rectum. The horizontal distance H from the directrix to any point, as P , on the parabola is equal to the direct distance D from the focus to that point (Fig. 6).

Problem 1.—At what points does the circle, whose radius is 3, intersect the parabola whose value of $n = 8$?

Solution.—circle: $y^2 = r^2 - x^2$
 parabola: $y^2 = 8x$
 (diff.) $x^2 + 8x = r^2 - 9$
 $\therefore x = 1; y = 2\sqrt{2}$ or $-2\sqrt{2}$.

Fig. 7.

Problem 2.—What is the equation of a parabola (that is, the value of n) whose base is 16, and altitude 12?

Solution.—When $x =$ the altitude $= 12$;
 $y =$ half the base $= 8$. Then $n = \frac{y^2}{x} = \frac{64}{12} = \frac{16}{3}$,
 and the equation of the above parabola is $y^2 = \frac{16}{3}x$, so y can be determined for any value of x (measured from the top downward). Thus, for $x = 3$ $y = \sqrt{16} = 4$; $x = 6$, $y = 4\sqrt{2}$; $x = 9$, $y = 4\sqrt{3}$; $x = 12$, $y = 4\sqrt{4} = 8$.

Fig. 8.

Equation of Tangent to the parabola: $y_1 y = \frac{n}{2}(x + x_1)$.

Equation of Normal to the parabola: $y_1 x + \frac{n}{2}y = x_1 y_1 + \frac{n}{2}y_1$.

Radius of Curvature r of the parabola $y^2 = nx$ is,

$$\text{At any point, } r = \frac{4}{n^2} \left(y^2 + \frac{n^2}{4} \right)^{\frac{3}{2}}.$$

$$\text{At the vertex, } O, r = \frac{n}{2}.$$

Note.—The equation of the parabola is variously given as $y^2 = nx$, $y^2 = 2px$, $y^2 = 4ax$, etc. It is plain that in these equations $n = 2p = 4a$, etc.

Ellipse.—The ellipse is a flattened circle.

Equation: $\frac{x^2}{a^2} + \frac{y^2}{b^2} = 1$, whence $b^2 x^2 + a^2 y^2 = a^2 b^2$;

$$x = \pm \frac{a}{b} \sqrt{b^2 - y^2}; y = \pm \frac{b}{a} \sqrt{a^2 - x^2};$$

$$a = \frac{bx}{\pm \sqrt{b^2 - y^2}} = \text{semi-major axis};$$

$$b = \frac{ay}{\pm \sqrt{a^2 - x^2}} = \text{semi-minor axis}.$$

Fig. 9.

Foci (singular, *focus*). F_1 and F_2 are foci, so situated that the length of any broken line $F_1 P_1 F_2$, joining any point P_1 of the curve, is a constant. Therefore, the distance from either focus to either extremity of the minor axis is equal to one-half the major axis, or a .

Problem.—The major axis of an ellipse is 20 ($a=10$), and the minor axis 10 ($b=5$). For a point P whose abscissa $x=6$, what is the value of the ordinate y ? (See Fig. 9.)

Solution.— $y = \frac{b}{a} \sqrt{a^2 - x^2} = \frac{5}{10} \sqrt{100 - 36} = \frac{1}{2} \sqrt{64} = 4$. *Ans.*

Tangent to the ellipse. Let T (Fig. 10) be the tangent point of the tangent PT to the *auxiliary circle*; then will the point t , lying vertically under T , be the tangent point of the tangent Pt to the ellipse, drawn from the same point P , lying on the major axis.

Equation of Tangent to the ellipse: $b^2 x_1 x + a^2 y_1 y = a^2 b^2$.

Equation of Normal to the ellipse: $a^2 y_1 x - b^2 x_1 y = (a^2 - b^2) x_1 y_1$.

Radius of Curvature r of the ellipse $\frac{x^2}{a^2} + \frac{y^2}{b^2} = 1$ is,

$$\text{At any point, } r = \frac{(a^4 y^2 + b^4 x^2)^{\frac{3}{2}}}{a^4 b^4}$$

$$\text{At extremity of major axis, } r = \frac{b^2}{a}.$$

$$\text{At extremity of minor axis, } r = \frac{a^2}{b}.$$

The *false ellipse* or *oval* is simply an approximation to the true ellipse. For instance, the true ellipse consists of an *infinite* number of infinitesimal arcs with radii gradually decreasing in length from $r = \frac{a^2}{b}$ at extremity of

minor axis, to $r = \frac{b^2}{a}$ at extremity of major axis; whereas the false ellipse or oval consists of a *definite* number of arcs with radii decreasing as above. The semi-false ellipse is sometimes called a *many-centered arch*; the most common forms for bridges are the 5-centered and 3-centered. These terms may also be applied to the false elliptic arc even if it comprises only part of the semi-false ellipse.

Fig. 10.

Fig. 11.

Hyperbola (Fig. 11).—Equation: $\frac{x^2}{a^2} - \frac{y^2}{b^2} = 1$, or $b^2 x^2 - a^2 y^2 = a^2 b^2$ (1)

$$\text{whence, } x = \pm \frac{a}{b} \sqrt{b^2 + y^2}; \quad y = \pm \frac{b}{a} \sqrt{x^2 - a^2};$$

$$a = \frac{bx}{\pm \sqrt{b^2 + y^2}}; \quad b = \frac{ay}{\pm \sqrt{x^2 - a^2}}.$$

Problem.—In a hyperbola the coordinates of a point P are, $x=6$, $y=4\sqrt{3}$; and $a=3$. Find the value of b so that other points can be plotted?

$$\text{Solution.}—b = \frac{ay}{\pm \sqrt{x^2 - a^2}} = \frac{3 \times 4\sqrt{3}}{\pm \sqrt{36 - 9}} = \frac{12\sqrt{3}}{\pm 3\sqrt{3}} = \pm 4.$$

Then for any point, $y = \pm \frac{b}{a} \sqrt{x^2 - a^2}$; and $x = \pm \frac{a}{b} \sqrt{b^2 + y^2}$.

Equation of Tangent to the hyperbola: $b^2 x_1 x - a^2 y_1 y = a^2 b^2$.

Equation of Normal to the hyperbola: $a^2 y_1 x + b^2 x_1 y = (a^2 + b^2) x_1 y_1$.

Equilateral Hyperbola.—The hyperbola becomes equilateral when the asymptotes are perpendicular to each other: hence the two axes, $2a$ and $2b$ (Fig. 11) are equal: hence $a = b$ in Equation (1), page 259.

The equilateral hyperbola is a very useful curve. It enters into the solution of the Howe-truss brace problem (see Section 33).

Fig. 12.

Cycloid (Fig. 12).—Equation: $x = r \text{ vers }^{-1} \frac{y}{r} - \sqrt{2ry - y^2}$, in which $\text{vers }^{-1} \frac{y}{r}$

= the angle, in circular measure, whose $\text{vers} = \frac{y}{r}$.

Hence, $x = r\alpha_1 - ND = OD - ND = ON$ (Fig. 12). Also,

$$x = r(\alpha_1 - \sin \alpha); (\alpha_1 = 0.0174533 \alpha \text{ in degrees.})$$

$$y = r(1 - \cos \alpha) = r \text{ vers } \alpha;$$

$$r = x + (\alpha_1 - \sin \alpha) = y + \text{vers } \alpha.$$

Radius of Curvature $r = 2\sqrt{2ry} =$ twice the length of the normal. (The normal to the curve at p is a straight line pD .)

For other Properties of the Cycloid, see page 236.

Catenary and Modified Catenary.—(See Suspension Bridges, and Arches.)

Spiral of Archimedes.—Equation: $r = a\theta$.

Logarithmic Spiral.—Equation: $r = a^\theta$.

Hyperbolic Spiral.—Equation: $r\theta = a$.

Lemniscate of Bernoulli.—Equation: $r^2 = a^2 \cos 2\theta$.

Helix or Screw.—A line traced from a fixed point bearing on a cylinder which is made to revolve, and at the same time to advance, uniformly. The *pitch* = the spacing of the lines or threads of the screw. Note that if the cylinder is developed, i. e., represented on a flat surface, all the lines or threads will be straight.

Common Spiral.—A line traced from a point bearing on a revolving plate and advancing uniformly outward from its center.

13.—DESCRIPTIVE GEOMETRY.

Descriptive Geometry deals with graphical methods of representing magnitudes and of solving problems in Geometry.

Perspective pictures an object as if seen from a finite distance. Fig. 1 shows the perspective of a rectangular box. Points VP are *vanishing points* on the *horizon line* HL , which is supposed to be on a level with the eye. PS is the *point of sight*, directly opposite the eye and at the intersection of HL with the *vertical line* VL .

Fig. 1.

All lines which are parallel in the object must meet at a common vanishing point. If the lines are horizontal in the object the VP lies on the line VL , at an infinite distance from PS ; therefore, vertical lines in the object are shown vertical in the perspective. Note that the ground line, GL , is horizontal. The perspective of the object may occupy any position with reference to PS , HL , and VL ; i.e., HL may lie above or below the object, or cut it, and VL may lie to the right or left of the object, or cut it.

Cabinet projection pictures an object as if seen from an infinite distance. The ground line GL is at an angle of 45° with the horizontal, and lines parallel with its direction are drawn to $\frac{1}{2}$ scale. (Fig. 2.)

Fig. 2.

Isometric projection pictures an object as if seen from an infinite distance, with the ground line GL 30° with the horizontal; and all lines drawn to full scale. (Fig. 3.)

Fig. 3.

ORTHOGRAPHIC PROJECTION.

Orthographic projection, or Descriptive Geometry proper, deals graphically with the problems of position and dimension of the (point,) line, surface and solid in space. The ground line GL is the intersection of two coordinate planes, V (vertical) and H (horizontal), forming four dihedral angles—1st, 2nd, 3rd and 4th (Fig. 4).

Fig. 4.

Revolved planes.—In the isometric figure, Fig. 4, a is a point in space, ah is its vertical projection on the horizontal plane H , and a' is its horizontal projection on the vertical plane V ; further, a_0 is the horizontal projection of ah and the vertical projection of a' , on the ground line. If now the vertical plane V is revolved on the ground line GL , so as to coincide with the horizontal plane H , the projection a' of a will fall on a^v , so that the distance $a^v a_0 = a' a_0 = a ah$, and $ah a_0 = a a'$.

By revolving the ground line to a horizontal position as in Fig. 5, with the vertical plane above and the horizontal plane below, it will be seen that the point a in space may be represented by its projections, a^v and ah .

Fig. 5.

Projection of the point.—A point may be situated in the 1st, 2nd, 3rd or 4th dihedral angle, or it may be situated in one of the composite planes. Fig. 6 illustrates the system of lettering adopted to show the position of any point. A point in space is designated by a *small* letter, and its projection by the same letter with *v* or *h* written above, as an index.

Dihedral angle in which point is situated:
Plane " " " " " ;

Fig. 6.

Note.—In cases (2) and (4), lvh and nvh represent points l and n respectively equidistant from the coordinate planes.

Projection of the right line.—The position of a right line in space may be determined by the projection of two of its points. Fig. 7 illustrates the system of lettering adopted to show the position of any line. A line in space is designated by a *capital* letter, and its projection by the same letter with *v* or *h* written above, as an index.

Dihed ang: 1° 1° 2° 3° 4° 3° 1° 3° 1°
Plane:

Remarks.— B and K pierce H ; C , G and H pierce the ground line; I pierces V , and is parallel to H ; B and G are perpendicular to H ; and J is parallel to H and V .

Projection of two lines.

Remarks.—

(1). M and L intersect at a , therefore the projections of their intersection are a^v and ah .

(2). N and O are not in the same plane, as the intersections of their projections are not the projections of a common point.

(3). P and Q are parallel, as their common projections are parallel.

Note.—Two lines which are parallel or intersect, represent a plane, and the horizontal and vertical projections of their point of intersection must lie in the same perpendicular line.

Fig. 8.

Projection of the plane.—A plane is determined by three points, or a point and a right line, or two right lines parallel or intersecting. The lines of intersection of a plane in space with the coordinate planes are called *traces*. Fig. 9 shows the vertical and horizontal traces of various planes in the 1st dihedral angle.

Fig. 9.

Plane A, perpendicular to vertical plane.	Plane B, perpendicular to horizontal plane.	Plane C, perpendicular to both co- ordinate planes.	Traces of D make acute angles with ground line.	Traces of E. F make supplemen- tary angles with ground line.	Plane G, parallel to ground line.
---	---	---	---	---	---

Problems of Construction.—In problems of construction the following conventional lines are employed:

Principal lines (data and results), *full* when visible and *dots* when invisible.

Auxiliary lines (minor lines), small *dashes* and *dots*.

Construction lines, (joining projections of the same points in space), fine *dashes*.

Problem 1.—To find the projections of a line in space and also its length. (Fig. 10.)

A right line A in the 1st dihedral angle pierces the H plane at a point *n*, 3 ft. from the ground line, and the V plane at a point *m*, 5 ft. from the ground line; the distance between the projections of the points, measured parallel with the ground line, being 15 ft. What is the length of the line A in space?

Fig. 10.

Solution.—Let the points *n* and *m* be represented respectively by their vertical and horizontal projections n^v , n^h and m^v , m^h ; then will A^v , joining n^v and m^v , and A^h , joining n^h and m^h , be the respective vertical and horizontal projections of the line A; and the length of the line will equal A' or A'' , A' being the hypotenuse of a right triangle whose base is A^h and altitude 3 ft.; and A'' the hypotenuse of a right triangle with base A^h and altitude 5 ft. Hence, by scale, $A = 16.1$ ft. (Analytically, $A = \sqrt{15^2 + 5^2 + 3^2} = \sqrt{259} = 16.09$ ft.) Ans.

Problem 2.—To find where a given right line A, shown in the 1st dihedral angle, pierces the coordinate planes V and H? (Fig. 11.)

Solution.—Let A^v and A^h be the vertical and horizontal projections of the line A; then will m^h , the point where the horizontal projection of A intercepts the ground line, be the horizontal projection of the point where the line pierces the V plane (at m^v); and n^v , the point where the vertical projection of A intercepts the ground line, will be the vertical projection of the point where the line pierces the H plane (at n^h). Therefore, the line A pierces the (upper)

Fig. 11.

V plane at m^v , by scale 9 ft. from the ground line; and it pierces the (back) H plane at n^h , by scale 12 ft. from the ground line; the points being horizontally (parallel with the ground line) $17\frac{1}{2}$ ft. apart. It will be observed that the portion of the line between m^v and n^h is in the 2nd dihedral angle.

Problem 3.—To pass a plane P through three given points not in the same straight line. (Fig. 12.)

Fig. 12.

Solution.—Let m , n and o be three points in space, in the 1st dihedral angle, so that the horizontal distance (parallel with ground line) between the projections of m and n is 5 ft., and between those of n and o , is $2\frac{1}{2}$ ft. Also let the perpendicular distances from the points in space, to the coordinate planes be as follows: m to H , 6 ft.; m to V , 2 ft.; n to H , 4 ft.; n to V , 6 ft.; o to H , 8 ft., and o to V , 3 ft. That is, m is 6 ft. from the H plane and 2 ft. from the V plane, etc.

Let A^h be the horizontal projection of a line A passing through the points m and n , then A^h will pass through m^h and n^h ; also where A^h intercepts the ground line GL (Problem 2), p^h is the horizontal projection of the point where the line A pierces the V plane, at p^v . In a similar way, B^v and B^h are the vertical and horizontal projections of the line B , passing through the points n and o in space; and s^v and r^h are the points where the line pierces the V and H planes, respectively. It is evident that p^v and s^v are points on the vertical trace VP of the plane P , and that r^h and q^h lie in its horizontal trace, HP .

By scale, the tangent of the angle which the trace of each plane makes with the ground line is .400, and the point of intersection, at G , of the two traces at the ground line, is distant 20 ft. from m^o of point m .

This problem is very useful in structural shop details, such as finding the end bevel of hip and valley rafters, in framing, etc.

Problem 4.—To find the point b where a perpendicular line L from a given point a pierces a given plane P ; also the length of L . (Fig. 13.)

Data.—Let a^v and a^h be the vertical and horizontal projections of the point a , and let VP and HP be the traces of the plane P .

Fig. 13.

a line in space is perpendicular to a plane, the projections are respectively perpendicular to the traces of the plane; Therefore, draw L^v from a^v perpendicular to VP , and L^h perpendicular to HP , as the vertical and horizontal projections of the line L perpendicular to the plane P . Find b^v and b^h , the vertical and horizontal projections of b . From the extremities of L^h lay off, at right angles, a^v , and b^h $b^v = b_0$ b^v . Then L' is the length of the line L .

To find the angle between two given planes, P and Q .

Let the two planes P and Q intersect at the line L . Draw a plane R through the line L , perpendicular to the line L . (it will also be perpendicular to Q (it will also be perpendicular to their common line L)). Cutting these planes P and Q , and cutting the horizontal trace of the planes at the lines R_1 and R_2 , measure the required angle between the planes.

Let the planes P and Q intersect at the line L at points 3 and 4 . The vertical trace VP makes an angle of 65° with the horizontal line; HP , an angle of 50° ; HQ , 60° . The required angle between the planes is α , as follows:

Fig. 14.

Fig. 15, lay the planes P and Q 3 ft. apart. The vertical traces VP and VQ make angles of 65° and 45° with the horizontal line; HP , an angle of 50° ; HQ , 60° . The required angle between the planes is α , as follows:

Fig. 15.

The angle between the planes P and Q is α . Revolve this triangle on VP until n , the apex of the triangle, fall at n'' , and on'' will be the required angle between the planes is α .

14.—THE CALCULUS.

The Calculus furnishes us with direct and exact methods for solving many problems which could be solved otherwise only by indirect approximations; and the application of its principles provides us with useful working formulas in Mensuration, Geometry, Mechanics and other subjects.

The two processes in calculus are *differentiation* and *integration*, each being the inverse of the other. The former comprises the subject of Differential Calculus, and is *analytic* in its nature; the latter comprises Integral Calculus, and is *synthetic*.

Problems to be solved by the *Differential Calculus* may be reduced to an equation which will be the equation of some curve referred to coordinate axes, as in Analytic Geometry. If there are two variables in the equation, as x and y , there will be two coordinate axes, X and Y . The process of *differentiation* enables us to find the *slope of the curve* at any point p whose coordinates are x and y ; and from this angle of slope, say with the axis of X , we may determine (1) the *actual change in y* for a corresponding change in x , and (2) the *rate of change in y* , at any point on the curve.

Problems to be solved by the *Integral Calculus* may be reduced to an equation which will be the equation of the *slope of some curve* referred to coordinate axes, as in Analytic Geometry. If there are two variables in the equation, as x and y , there will be two coordinate axes, X and Y . The process of *integration* enables us to find the *equation of the curve*, i. e., the value of the ordinate y for any value of the abscissa x .

A. DIFFERENTIAL CALCULUS.

Differentiation has for its main object the determination, from the equation of the problem, of—

1st, the *differential dy* , = the *actual change* in a function, due to a corresponding change dx of the variable x upon which it depends.

2nd, the *differential coefficient $\frac{dy}{dx}$* , = the *rate of change* of a function.

To illustrate: In the equation $y = x^2$ let y = the area of a square of which x is the side. Now increase x by the distance dx (reads "differential of x ," and does not mean $d \times x$), an amount *smaller than any numerical value*; then will the new area $y_1 = x_1^2 = (x + dx)^2 = x^2 + 2xdx + dx^2$; and the increment or actual change in y will be $dy = y_1 - y = x^2 + 2xdx + dx^2 - x^2 = 2xdx + dx^2$. But as any infinitesimal quantity, as dx or dx^2 , which is purely additive may be neglected, we have,

$$\text{differential } dy = 2xdx,$$

and the differential coefficient $\frac{dy}{dx} = 2x = \frac{2x}{1}$.

Fig. 1.

Differential Coefficient.—The differential coefficient is simply the natural tangent of the angle which a tangent to a curve makes with the axis of X .

The preceding equation, $y = x^2$, is the equation of the parabola, $y = nx^2$ (see Analytic Geometry), in which $n = 1$. Let Fig. 2 represent such a curve and let x and y be the coordinates of any point p . Also let p' be another point so that $x + dx = x'$ and $y + dy = y'$; then will $\frac{dy}{dx} =$

Fig. 2.

* Note that dy = increment of $y = y' - y$,
and dx = increment of $x = x' - x$.

the angle θ of a straight line passing through the points pp' are practically identical, as dx is smaller; hence the line tt' , passing through the point p on the curve at the point p whose coordinates are x and y .

the length of the side of a square whose area would be the side, for a small increment?

differential coefficient $\frac{dy}{dx}$ equal to 8 in equation (2),

= 4. Ans.

1. — We have seen, Fig. 2, that $\frac{dy}{dx} (= \frac{2x}{1})$ represents the tangent to the parabola passing through the point p and y . If, now, we assign a definite value to either, the other may be determined from the equation $y = x^2$,

Thus, let $x = \frac{1}{2}$; then $y = \frac{1}{4}$, and $\frac{dy}{dx} = 2x = 2 \times \frac{1}{2} = 1$.

the tangent to the curve at the point p whose coordinates are $\frac{1}{2}$, is $\frac{dy}{dx} = 1$; and hence the angle which it makes

This angle, 45° , means that for any increment in whose length is $\frac{1}{2}$, the area will receive an equal increment, let $x = 1\frac{1}{2}$; then, from $y = x^2$, $y = 2\frac{1}{4}$; and from

angle which the tangent to the curve at the point p makes with the axis of X , = the anti-tangent of $3 = 71^\circ - 34'$.

differential coefficient of y with respect to x , so is

differential coefficient of x with respect to y ; that is,

represents the slope of a normal to the parabola

se coordinates are x and y .

$\frac{dx}{dy}$ are, respectively, the slopes of the tangent and normal referred to the axis of X .

tion.—The differential coefficient of—
with respect to itself is 1.

$$= 8; \frac{dy}{dx} = 0.$$

any number of quantities is the algebraic sum of their parts.

$$+ \frac{dv}{dx}. \quad y = 4x^3 - 5x^2; \quad \frac{dy}{dx} = 12x^2 - 10x.$$

ables, is the sum of the products of each variable by the differential coefficient of the other.

$$+ u \frac{dv}{dx}. \quad y = 3x^2(4x + 1); \quad \frac{dy}{dx} = (4x + 1) 6x + (3x^2) 4.$$

stant and a variable, is the product of the constant differential coefficient of the variable.

$$y = 5x^3; \quad \frac{dy}{dx} = 5(3x^2).$$

- (f) *a fraction*, is the differential coefficient of the numerator multiplied by the denominator, minus the differential coefficient of the denominator multiplied by the numerator, this difference being divided by the square of the denominator.

$$y = \frac{u}{v}; \quad \frac{dy}{dx} = \frac{v \frac{du}{dx} - u \frac{dv}{dx}}{v^2}.$$

$$y = \frac{3x^2 + 2}{2x}; \quad \frac{dy}{dx} = \frac{2x(6x+0) - (3x^2+2)2}{4x^2} = \frac{3x^2 - 2}{2x^2}.$$

- (g) *any power of a variable*, is the product of the exponent, the power with exponent diminished by 1, and the differential coefficient of the variable.

$$y = u^n; \quad \frac{dy}{dx} = nu^{n-1} \frac{du}{dx}.$$

$$y = 2(x^2 + 3)^2; \quad \frac{dy}{dx} = (3 \times 2)(x^2 + 3)^2 \times 2x = 12x(x^2 + 3)^2.$$

Maxima and Minima.—One of the principal uses of the differential calculus is to find the maximum or minimum value of a function. In any curve, as for instance the ellipse, $a^2y^2 + b^2x^2 = a^2b^2$ (see Analytic Geometry), let it be required to find the maximum value of the ordinate y . From the above equation, placing y in the first member, we have $a^2y^2 = a^2b^2 - b^2x^2$. Differentiating, $2a^2y \, dy = 0 - 2b^2x \, dx$; whence the differential coefficient $\frac{dy}{dx} = -\frac{2b^2x}{2a^2y} = -\frac{b^2x}{a^2y}$ = tangent of

Fig. 3.

angle of inclination of the tangent $\#$, with the axis of X . That is, $-\frac{b^2x}{a^2y}$ is the value of m in the equation of the straight line $\#$. (See Analytic Geometry.)

For any tangent to the ellipse, if m is a *minus* quantity, the point of contact p is in the 1st or 3rd quadrants, and if it is a *plus* quantity the point of contact is in the 2nd or 4th quadrants. This is made evident by noting whether the tangent line $\#$ slopes upward to the right or downward to the right. If the point of contact p is in the first quadrant, x and y are *plus*

and $\frac{dy}{dx} = -\frac{b^2}{a^2} \left(\frac{x}{y} \right) = -\frac{b^2x}{a^2y}$; if in the second quadrant, x is *minus* and y is *plus*

hence $\frac{dy}{dx} = -\frac{b^2}{a^2} \left(\frac{-x}{y} \right) = \frac{b^2x}{a^2y}$; if in the 3rd quadrant, $\frac{dy}{dx} = -\frac{b^2}{a^2} \left(\frac{-x}{-y} \right)$

$= -\frac{b^2x}{a^2y}$; and if in the 4th quadrant, $\frac{dy}{dx} = -\frac{b^2}{a^2} \left(\frac{x}{-y} \right) = \frac{b^2x}{a^2y}$. Thus, we are able

to study the slope of a curve at any point.

By inverse analysis we may find the values of x and y (including the maximum and minimum values) by assigning definite values to the slope

$\frac{dy}{dx}$. Thus, when y is a maximum we know that the tangent line $\#$ must

move so as to be parallel with the axis of X ; hence, it will coincide with the tangent line TT , touching the point P at the upper extremity of the minor

axis; or with a parallel tangent through the point P' at its lower extremity. And, when y is a minimum, $\#$ will be perpendicular to the axis of X , touching points on the curve at either extremity of the major axis. In the former

case, $\frac{dy}{dx} \left(-\pm \frac{b^2x}{a^2y} \right) = 0$; whence $x = 0$, which value substituted in the general equation makes $y = \pm b$, a maximum. And in the latter case

$\frac{dy}{dx} \left(-\pm \frac{b^2x}{a^2y} \right) = \infty$; whence $y = 0$, a minimum.

Maxima and Minima obtain at points where $\frac{dy}{dx}$ changes from + to - or from - to +.

Problem 1.—It is desired to suspend a weight W vertically beneath a point P situated midway between two level supports A and B . For this purpose two diagonal rods, AW and BW , of equal length, are used. At what angle α shall the rods be inclined so that a minimum amount of metal will be required?

Fig. 4.

Solution.—The stress in each rod $= \frac{W}{2} \sec \alpha$, and the length of each rod $= d \csc \alpha = k \sec \alpha$; hence, the amount of metal required in the rods would be, making n a constant, and k variable,

$$\begin{aligned} y &= n \left(\frac{W}{2} \sec \alpha \right) (k \sec \alpha) \\ &= \frac{nkW}{2} \sec^2 \alpha = \frac{nkW}{2} (1 + \tan^2 \alpha) \\ &= \frac{nkW}{2} + \frac{nkW}{2} \cdot \frac{d^2}{k^2} \\ &= \frac{nkW}{2} + \frac{n d^2 W}{2k}. \end{aligned}$$

$$\text{whence } \frac{dy}{dk} = \frac{nW}{2} - \frac{2n d^2 W}{4k^2} = 0, \text{ for minimum;}$$

$$\therefore 4nWk^2 = 4nWd^2 \\ \therefore k = d, \text{ or } \alpha = 45^\circ.$$

This proves that the most economical angle for a truss diagonal is 45° .

Problem 2.—It is proposed to build a railroad from A , a point opposite B and distant 30 miles, to D a point 50 miles below B . The cost of grading on the line BC is \$8,000 per mile, while the cost of grading from A diagonally to any point C is \$12,000 per mile. Find the position of the point C so that the entire cost of grading will be a minimum.

Fig. 5.

Solution.—Let y = the cost of grading the line, and from the data,

$$y = \$12,000 (\overline{AC}) + \$8,000 (\overline{BC}).$$

Let $BC = x$, $AB = 30$, and $BD = 50$; then

$$y = 12000 (900 + x^2)^{\frac{1}{2}} + 8000 (50 - x).$$

$$\frac{dy}{dx} = 6000 (900 + x^2)^{-\frac{1}{2}} (2x) - 8000 = 0 \text{ for minimum;}$$

$$\therefore \frac{12000x}{\sqrt{900 + x^2}} = 8000$$

$$\therefore x = 26.83 \text{ miles. Ans.}$$

Note.—The entire cost of construction and the cost of operation would of course enter as factors to reduce the distance between C and D , for economy.

Problem 3.—What is the maximum cylinder, in volume, that can be inscribed in a sphere?

Solution.—Let R = radius of sphere; r = radius, and h = altitude, of cylinder. Let V = volume of cylinder; then,

$$V = \pi r^2 h = \pi h \left(R^2 - \frac{h^2}{4} \right),$$

in which V = a function of h , both being variable, with R constant. Differentiating and making $\frac{dV}{dh} = 0$,

$$\text{we have, } \frac{dV}{dh} = \pi R^2 - \frac{1}{2} \pi h^2 = 0;$$

$$\therefore h = \frac{2}{\sqrt{3}} R = \frac{2}{3} \sqrt{3} R. \text{ Ans.}$$

Fig. 6.

Other Forms of Differentiation.—There are two forms in which the result of differentiation may be expressed, namely, *differential coefficient* or simply *differential*:

$$y = x^2; \quad \frac{dy}{dx} = 2x \quad \text{— differential coefficient.}$$

$$y = x^2; \quad dy = 2x \, dx \quad \text{— differential.}$$

Hence the differential coefficient $\frac{dy}{dx}$ may be considered as a fraction,

the numerator dy being the perpendicular, and the denominator dx the base, of an infinitesimal triangle of which the hypotenuse is equal to $\sqrt{dx^2 + dy^2}$. Multiplying the differential coefficient by dx we obtain the differential $dy = 2x \, dx$. It is well to keep this graphical analysis in mind in dealing with problems involving both Differential and Integral Calculus, as it then loses much of its haze and mystery.

Fig. 7.

Besides the Algebraic forms (a) to (g), which are *universal in their application*, the following formulas for differentiation of special functions will be found useful for reference. (For Algebraic Functions, see pages 267, 268.)

LOGARITHMIC AND EXPONENTIAL FUNCTIONS:

$$(h) \left\{ \begin{array}{l} y = \log_a x; \quad dy = \frac{\log_a e \, dx}{x} \\ y = \log_e x; \quad dy = \frac{dx}{x} \end{array} \right.$$

$$(i) \left\{ \begin{array}{l} y = \log_a u; \quad \frac{dy}{dx} = \log_a e \cdot \frac{\frac{du}{dx}}{u}; \quad dy = \log_a e \cdot \frac{du}{u} \\ y = \log_e u; \quad \frac{dy}{dx} = \frac{\frac{du}{dx}}{u}; \quad dy = \frac{du}{u} \end{array} \right.$$

$$(j) \quad y = a^u; \quad \frac{dy}{dx} = \log_e a \cdot a^u \frac{du}{dx}; \quad dy = \log_e a \cdot a^u \, du.$$

$$(k) \quad y = e^u; \quad \frac{dy}{dx} = e^u \frac{du}{dx}; \quad dy = e^u \, du.$$

$$(l) \quad y = u^v; \quad \frac{dy}{dx} = v u^{v-1} \frac{du}{dx} + \log_e u \cdot u^v \frac{dv}{dx}; \quad dy = v u^{v-1} \, du + \log_e u \cdot u^v \, dv.$$

TRIGONOMETRIC FUNCTIONS:

$$(m) \quad y = \sin u; \quad \frac{dy}{dx} = \cos u \frac{du}{dx}; \quad dy = \cos u \, du.$$

$$(n) \quad y = \cos u; \quad \frac{dy}{dx} = -\sin u \frac{du}{dx}; \quad dy = -\sin u \, du.$$

$$(o) \quad y = \tan u; \quad \frac{dy}{dx} = \sec^2 u \frac{du}{dx}; \quad dy = \sec^2 u \, du.$$

$$(p) \quad y = \cot u; \quad \frac{dy}{dx} = -\operatorname{cosec}^2 u \frac{du}{dx}; \quad dy = -\operatorname{cosec}^2 u \, du.$$

$$(q) \quad y = \sec u; \quad \frac{dy}{dx} = \sec u \tan u \frac{du}{dx}; \quad dy = \sec u \tan u \, du.$$

$$(r) \quad y = \operatorname{cosec} u; \quad \frac{dy}{dx} = -\operatorname{cosec} u \cot u \frac{du}{dx}; \quad dy = -\operatorname{cosec} u \cot u \, du.$$

$$(s) \quad y = \operatorname{vers} u; \quad \frac{dy}{dx} = \sin u \frac{du}{dx}; \quad dy = \sin u \, du.$$

VERSE TRIGONOMETRIC FUNCTIONS:

$$\frac{dy}{dx} = \frac{\frac{du}{dx}}{\sqrt{1-u^2}};$$

$$dy = \frac{du}{\sqrt{1-u^2}}.$$

$$\frac{dy}{dx} = -\frac{\frac{du}{dx}}{\sqrt{1-u^2}};$$

$$dy = -\frac{du}{\sqrt{1-u^2}}.$$

$$\frac{dy}{dx} = \frac{\frac{du}{dx}}{1+u^2};$$

$$dy = \frac{du}{1+u^2}.$$

$$\frac{dy}{dx} = -\frac{\frac{du}{dx}}{1+u^2};$$

$$dy = -\frac{du}{1+u^2}.$$

$$\frac{dy}{dx} = \frac{\frac{du}{dx}}{u\sqrt{u^2-1}};$$

$$dy = \frac{du}{u\sqrt{u^2-1}}.$$

$$\frac{dy}{dx} = -\frac{\frac{du}{dx}}{u\sqrt{u^2-1}};$$

$$dy = -\frac{du}{u\sqrt{u^2-1}}.$$

$$\frac{dy}{dx} = \frac{\frac{du}{dx}}{\sqrt{2u-u^2}};$$

$$dy = \frac{du}{\sqrt{2u-u^2}}.$$

EXPANSION OF FUNCTIONS.

$$\frac{1}{1+x} = 1 - x + x^2 - x^3 + x^4 - \dots.$$

ation is employed in the expansion of functions and

Let $y = u$ be any equation in which u is a function

differential coefficient $\left(= \frac{dy}{dx} \right)$ is the diff coef of y ;

$\left(= \frac{d^2y}{dx^2} \right)$ is the diff coef of the first diff coef; the 3rd diff

coef of the 2nd diff coef, etc. For example, let $y = 3x^4$;

$12x^3$, etc.

m enables us to expand into a series any function u by the use of successive differential coefficients. Let u be expanded, and assume

$u = A + Bx + Cx^2 + \dots$, using Indeterminate Coefficients. (1)

value of u successively and making $x=0$ in all variations, we have,

Making $x=0$:

$$y = A, \quad \text{or } A = y.$$

$$Ex^1 \text{---}, \quad \frac{dy}{dx} = B, \quad \text{or } B = \frac{dy}{dx}.$$

$$Ex^2 \text{---}, \quad \frac{d^2y}{dx^2} = 2C, \quad \text{or } C = \frac{1}{2} \left(\frac{d^2y}{dx^2} \right).$$

$$\text{---}, \quad \frac{d^3y}{dx^3} = 2 \cdot 3 D, \quad \text{or } D = \frac{1}{2 \cdot 3} \left(\frac{d^3y}{dx^3} \right).$$

$$\frac{d^4y}{dx^4} = 2 \cdot 3 \cdot 4 E, \quad \text{or } E = \frac{1}{2 \cdot 3 \cdot 4} \left(\frac{d^4y}{dx^4} \right).$$

etc.

Substituting the above values of the indeterminate coefficients in equation (1) we have the following working equation:

$$u = y + \frac{dy}{dx} \cdot x + \frac{d^2y}{dx^2} \cdot \frac{x^2}{2} + \frac{d^3y}{dx^3} \cdot \frac{x^3}{2 \cdot 3} + \frac{d^4y}{dx^4} \cdot \frac{x^4}{2 \cdot 3 \cdot 4} + \dots \quad (2)$$

remembering that $y = u$ when, in all the successive differential coefficients, $x = 0$.

Examples in the use of equation (2).—It is to be noted that Maclauren's Theorem may be considered a *special case* of Taylor's Theorem, following. Also, the Binomial Formula (see Algebra) is a special case of Maclauren's Theorem.

Expansion of a few common functions:

$$\log_e (1+x) = x - \frac{x^2}{2} + \frac{x^3}{3} - \frac{x^4}{4} + \frac{x^5}{5} - \dots \quad \text{Naperian system.}$$

$$\log_a (1+x) = M \left(x - \frac{x^2}{2} + \frac{x^3}{3} - \frac{x^4}{4} + \frac{x^5}{5} - \dots \right) \quad \text{Common system.}$$

$$\therefore M = \frac{\text{Common log } (1+x)}{\text{Naperian log } (1+x)} = \frac{1}{2.30258509} = .4342944819 = \text{the modulus of the common system} = \text{common log } e = \log_a e.$$

$$e = 2 + \frac{1}{2} + \frac{1}{2 \cdot 3} + \frac{1}{2 \cdot 3 \cdot 4} + \frac{1}{2 \cdot 3 \cdot 4 \cdot 5} + \dots = 2.718281828 +.$$

$$e^x = 1 + \frac{x}{1} + \frac{x^2}{1 \cdot 2} + \frac{x^3}{1 \cdot 2 \cdot 3} + \frac{x^4}{1 \cdot 2 \cdot 3 \cdot 4} + \dots$$

$$\sin \alpha = \alpha_1 - \frac{\alpha_1^3}{1 \cdot 2 \cdot 3} + \frac{\alpha_1^5}{1 \cdot 2 \cdot 3 \cdot 4 \cdot 5} - \frac{\alpha_1^7}{1 \cdot 2 \cdot 3 \cdot 4 \cdot 5 \cdot 6 \cdot 7} + \dots;$$

$$\text{thus, nat sine of } 30^\circ = \frac{\pi}{6} - \frac{1}{\lfloor 3} \left(\frac{\pi}{6} \right)^3 + \frac{1}{\lfloor 5} \left(\frac{\pi}{6} \right)^5 - \frac{1}{\lfloor 7} \left(\frac{\pi}{6} \right)^7 + \dots$$

$$\cos \alpha = 1 - \frac{\alpha_1^2}{1 \cdot 2} + \frac{\alpha_1^4}{1 \cdot 2 \cdot 3 \cdot 4} - \frac{\alpha_1^6}{\lfloor 6} + \frac{\alpha_1^8}{\lfloor 8} - \dots;$$

$$\text{thus, nat cos of } 20^\circ = 1 - \frac{1}{\lfloor 2} \left(\frac{\pi}{9} \right)^2 + \frac{1}{\lfloor 4} \left(\frac{\pi}{9} \right)^4 - \frac{1}{\lfloor 6} \left(\frac{\pi}{9} \right)^6 + \dots$$

$$\frac{\pi}{4} = 1 - \frac{1}{\lfloor 2} + \frac{1}{\lfloor 4} - \frac{1}{\lfloor 6} + \frac{1}{\lfloor 8} - \dots \quad \therefore \pi = 3.1415926536.$$

Taylor's Theorem enables us to expand a function of the sum of two variables arranged according to the ascending powers of one of the variables. Let u , = a function of $(x+h)$, be the function to be developed. Then, for a working formula,

$$u = y + \frac{dy}{dx} \cdot h + \frac{d^2y}{dx^2} \cdot \frac{h^2}{2} + \frac{d^3y}{dx^3} \cdot \frac{h^3}{1 \cdot 2 \cdot 3} + \dots \quad (3)$$

remembering that $y = u$ when, in all the successive differential coefficients of u , $h = 0$. (See Maclauren's Theorem, preceding, for illustration.)

Expansion of a few common functions:

$$\log (x+h) = \log x + \frac{h}{x} - \frac{h^2}{2x^2} + \frac{h^3}{3x^3} - \frac{h^4}{4x^4} + \dots$$

$$\tan (x+h) = \tan x + h \sec^2 x + h^2 \sec^2 x \tan x + \frac{h^3}{3} \sec^2 x (1 + 3 \tan^2 x) + \dots$$

$$\log (1 + \sin x) = x - \frac{x^2}{2} + \frac{x^3}{6} - \frac{x^4}{12} + \dots$$

B. INTEGRAL CALCULUS.

Integral Calculus is the process of *summation* or the adding up of an infinite number of infinitesimal quantities. Its operation is the inverse of differentiation. In the equation $y = x^2$, by differentiation we have $dy =$

$2x dx$, hence the summation or integration of $2x dx = \int 2x dx = x^2 \left(-2 \frac{x^2}{2} \right)$.

Suppose, for example, we wish to find the *area* of a triangle whose altitude

is h and base b , Fig. 8. If we let dA represent, in general, the area of any vertical strip of length y and width dx , distant x from the axis of Y , then the total area of the triangle will equal the summation of all these strips between the limits $x=b$ and

$$x=0; \text{ or, area } = A = \int_{x=0}^{x=b} dA = \int_{x=0}^{x=b} y dx.$$

The main difficulty in Integral Calculus is in forming the equations to be integrated and recognizing them as related to certain fundamental forms whose integrals are well known, many of which are given in tabular form in the following pages. In the above case, x and y are dependent variables, x increasing as y decreases, and vice versa. When $x=b$, $y=0$; when $x=0$, $y=h$; and the point P , whose coordinates are x and y , moves along the hypotenuse in a straight line between the axes of X and Y , as x and y vary. The equation of this straight line, of which $y=mx+b$ is the general equation, is

$$y = -\frac{h}{b}x + h$$

because the tangent of inclination m of the hypotenuse with the axis of X is $-\frac{h}{b}$ (minus, because downward to the right), and the value of b where the hypotenuse intercepts the axis of Y is h . But $dA = ydx$ = the area of an infinitesimal strip of length y , and from the above equation, $ydx = -\frac{h}{b}x dx + hdx$; hence,

$$\text{Area } = A = \int_{x=0}^{x=b} -\frac{h}{b}x dx + hdx$$

which, by certain fundamental forms given in the table, reduces to

$$A = -\frac{h}{b} \cdot \frac{x^2}{2} + hx.$$

Substituting the value of $x=b$ in the equation, we have

$$\text{Area } A = -\frac{h}{b} \cdot \frac{b^2}{2} + hb = \frac{1}{2}bh. \text{ Ans.}$$

Definite Integration a Method of Limits.—In the preceding illustration of the area of the triangle we referred to the upper limit $x=b$, and the lower limit $x=0$. We will now find the area of a *part* of the triangle or that etched portion, Fig. 8, between the upper limit $x=\frac{1}{2}b$, and the lower limit $x=\frac{1}{4}b$.

Thus,

$$A_1 = \int_{x=\frac{1}{4}b}^{x=\frac{1}{2}b} -\frac{h}{b}x dx + hdx$$

After integrating,

$$A_1 = \left[-\frac{h}{b} \frac{x^2}{2} + hx \right]_{x=\frac{1}{4}b}^{x=\frac{1}{2}b}$$

Substituting $\frac{1}{2}b$ and $\frac{1}{4}b$ for x ,

$$A_1 = \left(-\frac{h}{2b} \cdot \frac{9b^2}{16} + \frac{1}{2}bh \right) - \left(-\frac{h}{2b} \cdot \frac{b^2}{16} + \frac{1}{4}bh \right)$$

$\therefore$ partial area $A_1 = \frac{bh}{4}$. Ans.

Note.—Subtract the value obtained by using the lower limit, from the value obtained by using the upper limit.

Fig. 8.

Formulas for Integration.—

- (A) $\int ax^n dx = \frac{ax^{n+1}}{n+1}$. $\int x^5 dx = \frac{x^6}{6}$; $\int 2x^3 dx = 2 \cdot \frac{x^4}{4} = \frac{x^4}{2}$.
- (B) $\int \frac{dx}{x} = \log x$. $\int \frac{adx}{x} = a \log x$.
- (C) $\int a^x dx = \frac{a^x}{\log a}$. $\int a^x \log a dx = a^x$.
- (D) $\int e^x dx = e^x$. $\int a^{xe^x} dx = \frac{a^{xe^x}}{1 + \log a}$.
- (E) $\int \cos x dx = \sin x$. $\int \cos 2x dx = \sin(x+a) \cos(x-a)$.
- (F) $\int \sin x dx = -\cos x$. $\int \frac{2dx}{\sin 2x} = \log \tan x$.
- (G) $\int \sec^2 x dx = \tan x$.
- (H) $\int \operatorname{cosec}^2 x dx = -\cot x$. $\int \operatorname{cosec} x dx = \log \sqrt{\frac{1 - \cos x}{1 + \cos x}}$.
- (I) $\int \sec x \tan x dx = \sec x$.
- (J) $\int \operatorname{cosec} x \cot x dx = -\operatorname{cosec} x$.
- (K) $\int \tan x dx = \log \sec x$.
- (L) $\int \cot x dx = \log \sin x$.
- (M) $\int \sec x dx = \log (\sec x + \tan x) = \log \tan \left(\frac{x}{2} + \frac{\pi}{4} \right)$.
- (N) $\int \operatorname{cosec} x dx = \log (\operatorname{cosec} x - \cot x) = \log \tan \frac{x}{2} = \log \sqrt{\frac{1 - \cos x}{1 + \cos x}}$.
- (O) $\int \frac{dx}{x^2 + a^2} = \frac{1}{a} \tan^{-1} \frac{x}{a} = -\frac{1}{a} \cot^{-1} \frac{x}{a}$.
- (P) $\int \frac{dx}{x^2 - a^2} = \frac{1}{2a} \log \frac{x-a}{x+a} = \frac{1}{2a} \log \frac{a-x}{a+x}$.
- (Q) $\int \frac{dx}{\sqrt{a^2 - x^2}} = \sin^{-1} \frac{x}{a} = -\cos^{-1} \frac{x}{a}$.
- (R) $\int \frac{dx}{\sqrt{x^2 \pm a^2}} = \log (x + \sqrt{x^2 \pm a^2})$.
- (S) $\int \frac{dx}{a\sqrt{x^2 - a^2}} = \frac{1}{a} \sec^{-1} \frac{x}{a} = -\frac{1}{a} \operatorname{cosec}^{-1} \frac{x}{a}$.
- (T) $\int \frac{dx}{\sqrt{2ax - x^2}} = \operatorname{vers}^{-1} \frac{x}{a}$.

$$(U) \int \sqrt{a^2 - x^2} dx = \frac{x}{2} \sqrt{a^2 - x^2} + \frac{a^2}{2} \sin^{-1} \frac{x}{a}.$$

$$(V) \int x^2 \sqrt{a^2 - x^2} dx = \frac{x}{8} (2x^2 - a^2) \sqrt{a^2 - x^2} + \frac{a^4}{8} \sin^{-1} \frac{x}{a}.$$

Areas of Plane Curves.—

Formula (1). $A = \int_{a_1}^{a_2} y dx$ (Fig. 9.)

Formula (2). $A = \int_{b_1}^{b_2} (a - x) dy$ (Fig. 10.)

Fig. 9.

Let Figs. 9 and 10 each represent one-half a parabola whose base is $2b$ and altitude a . Required the area of the figure? From the general equation of the parabola, $y^2 = nx$, $n = \frac{y^2}{x}$. When $x = a$, $y = b$; therefore $n = \frac{b^2}{a}$, and the equation of the parabola in the figure is $y^2 = \frac{b^2}{a} x$. From this equation, $y = b \frac{x^{\frac{1}{2}}}{a^{\frac{1}{2}}}$ and $x = \frac{ay^2}{b^2}$.

Fig. 10.

Method (1), vertical strips.

$$A = \int_0^a y dx = \int_0^a \frac{b}{a^{\frac{1}{2}}} x^{\frac{1}{2}} dx \\ = \left[\frac{b}{a^{\frac{1}{2}}} \cdot \frac{x^{\frac{3}{2}}}{\frac{3}{2}} \right]_0^a$$

Method (2), horizontal strips.

$$A = \int_0^b (a - x) dy = \int_0^b \left(a - \frac{ay^2}{b^2} \right) dy \\ = \left[ay - \frac{a}{b^2} \frac{y^3}{3} \right]_0^b$$

Equivalent values. $-\frac{1}{3}ab$. Ans. $-ab - \frac{1}{3}ab = -\frac{4}{3}ab$. Ans.

It is thus seen that the same result, $\frac{4}{3}ab$, is obtained whether we assume the strips to be vertical and summate horizontally or whether we assume the strips to be horizontal and summate vertically.

Again, required the area of the shaded portion of the parabola in Fig. 9, Formula (1), between the limits $a_2 = 4$ and $a_1 = 2$:

$$A_1 = \int_2^4 y dx = \int_2^4 \frac{b}{a^{\frac{1}{2}}} x^{\frac{1}{2}} dx = \left[\frac{b}{a^{\frac{1}{2}}} \frac{x^{\frac{3}{2}}}{\frac{3}{2}} \right]_2^4 \\ = \frac{16}{3} \cdot \frac{b}{\sqrt{a}} - \frac{4\sqrt{2}}{3} \cdot \frac{b}{\sqrt{a}} = \frac{16 - 4\sqrt{2}}{3} \cdot \frac{b}{\sqrt{a}}. \text{ Ans.}$$

Lengths of Plane Curves.—

Formula: Length $L = \int dL = \int \sqrt{dx^2 + dy^2}$. (See Fig. 7.)

Use $L = \int \left[1 + \left(\frac{dy}{dx} \right)^2 \right]^{\frac{1}{2}} dx$, when x is the independent variable.

Use $L = \int \left[1 + \left(\frac{dx}{dy} \right)^2 \right]^{\frac{1}{2}} dy$, when y is the independent variable.

Problem.—The catenary, $y = \frac{a}{2} \left(e^{\frac{x}{a}} + e^{-\frac{x}{a}} \right)$, is the curve which a cable assumes when suspended at both ends, as at A and B , Fig. 11. Required the length of the catenary from the vertex V , on the axis of Y , to any point p whose coordinates are x and y ?

Fig. 11.

Solution.—
$$y = \frac{a}{2} \left(e^{\frac{x}{a}} + e^{-\frac{x}{a}} \right)$$

hence, $\frac{dy}{dx} = \frac{1}{2} \left(e^{\frac{x}{a}} - e^{-\frac{x}{a}} \right)$

and $dL = \frac{1}{2} \left(e^{\frac{x}{a}} + e^{-\frac{x}{a}} \right) dx \left(-\sqrt{1 + \left(\frac{dy}{dx} \right)^2} dx \right)$

with limits $x=x$, and $x=0$, $L = \frac{1}{2} \int_0^x \left(e^{\frac{x}{a}} + e^{-\frac{x}{a}} \right) dx$

$\therefore$ length from V to $P = L = \frac{a}{2} \left(e^{\frac{x}{a}} - e^{-\frac{x}{a}} \right)$. Ans.

Areas of Curved Surfaces, or surfaces of revolution.—

Formula (1). $S = 2\pi \int y ds = 2\pi \int y \left[1 + \left(\frac{dy}{dx} \right)^2 \right]^{\frac{1}{2}} dx$. (About axis of X .)

Formula (2). $S = 2\pi \int x ds = 2\pi \int x \left[1 + \left(\frac{dx}{dy} \right)^2 \right]^{\frac{1}{2}} dy$ (About axis of Y .)

Fig. 12.

Problem.—Let it be required to find the area of the shaded zone of a sphere of radius r , Fig. 12.

Solution.—Use Formula (1):

Equation of circle is $x^2 + y^2 = r^2$,
whence, $y^2 = r^2 - x^2$ or $y = \sqrt{r^2 - x^2}$.

$$\frac{dy}{dx} = -\frac{x}{y} \quad \text{and} \quad \left(\frac{dy}{dx}\right)^2 = \frac{x^2}{y^2}.$$

Substituting value of $\left(\frac{dy}{dx}\right)^2$ in Formula (1) there is obtained,

$$\begin{aligned} S &= 2\pi \int_{x=a}^{x=b} y \left(1 + \frac{x^2}{y^2}\right)^{\frac{1}{2}} dx \\ &= 2\pi \int_{x=a}^{x=b} (y^2 + x^2)^{\frac{1}{2}} dx = 2\pi \left[\frac{rx}{2} - 2\pi r(b-a) \right]. \text{ Ans.} \end{aligned}$$

Volumes, or planes of revolution.—

Formula (1). $V = \pi \int_{x=b}^{x=a} y^2 dx$ (Plane revolved about axis of X.)

Formula (2). $V = \pi \int_{y=d}^{y=c} x^2 dy$ (Plane revolved about axis of Y.)

Fig. 13.

Problem.—Find the volume generated by the shaded portion of the parabola $y^2 = 4x$, Fig. 13, about the axis of X.

Solution.—From the equation of the parabola and Formula (1), we have,

$$\begin{aligned} V &= \pi \int_b^a y^2 dx = \pi \int_b^a 4x dx \\ &= \pi \left[2x^2 - 2\pi(a^2 - b^2) \right]. \text{ Ans.} \end{aligned}$$

15.—MECHANICS.

General Discussion.

The subject of Mechanics deals fundamentally with *matter as matter at rest and in motion*; and with its accompanying phenomena.

All matter has *weight* (W) and its *mass* (M), for any particular locality, is directly proportional to its weight.

The weight of a body is the attractive *force* (F) of gravity existing between that body and the earth.

Motion is a purely relative term: used to express the relation existing between two or more bodies when one or more of them is in a state "unrest."

If a body starting from rest is allowed to fall unrestrained toward the earth, its *rate of motion*, or *velocity* (v), through *space* (h or s) will increase constantly with the *time* (t) occupied in its descent, and this *increase in velocity* per second of time is called *acceleration* (g) or (a).

Such a motion as described is called *uniformly accelerated motion*, the reverse of *uniformly retarded motion*; each of which is a form of *uniformly varying motion*.

Moreover, if, during its descent and after the body has acquired certain velocity, the action of gravity should suddenly cease, then acceleration would also cease and the body would continue with a constant *uniform motion*.

Fundamental Equations of Motion and Force.—In their relations one another, any force F acting on a mass M so as to produce acceleration a , may be considered analogous to the force of gravity W acting on a mass M and producing gravity acceleration g . Thus,

Weight = mass $\times$ g acceleration. Or,
 $W = Mg = \frac{Fg}{a}$; $g = \frac{W}{M} = \frac{Wa}{F}$; $M = \frac{W}{g}$.

Force = mass $\times$ a acceleration. Or,
 $F = Ma = \frac{W a}{g}$; $a = \frac{F}{M} = \frac{Fg}{W}$; $M = \frac{F}{a}$.

Fig. 1.

Fig. 2.

Ex. 1.—A car weighing 60 tons is impelled on a level track by a horizontal force of 1 ton. Assuming the rolling friction at 8 lbs. per ton, find the acceleration?

$$\text{Ans.} \quad a = \frac{Fg}{W} = \frac{(2000 - 480) 32.2}{60 \times 2000} = 0.408 \text{ ft. per sec.}$$

Note.—The acceleration $\times$ the length of time of the acting force = the velocity in ft. per second (see Ex. 3).

MOTION.

I. Uniform motion: v_0 constant, no acceleration.—With uniform motion a body moves at a constant velocity v_0 , imparted to it by a force which has been removed; hence there is no acceleration. Note that v_0 becomes the initial velocity in uniformly varying (accelerated or retarded) motions, following.

$$v_0 = \frac{h}{t} = \frac{h_1}{t_1} = \frac{h-h_1}{t-t_1}; h = v_0 t; t = \frac{h}{v_0}.$$

Fig. 3.

$$v_0 = \frac{s}{t} = \frac{s_1}{t_1} = \frac{s-s_1}{t-t_1}; s = v_0 t; t = \frac{s}{v_0}.$$

Fig. 4.

Ex. 2.—What velocity will be required to travel 16 miles in three-quarters of an hour?

$$\text{Ans.} \quad v_0 = \frac{s}{t} = \frac{16 \times 5280}{45 \times 60} = 31.29 \text{ ft. per sec.}$$

Relative uniform motion.—A man walking forward with a velocity v_0' , in a train moving with a velocity v_0'' , acquires an actual velocity of $V_0 = v_0' + v_0''$. Similarly, if walking backward in the train he would acquire a velocity of $v_0 = v_0' - v_0''$, in the direction in which he is walking; or, $v_0 = v_0'' - v_0'$, in the direction of the moving train.

II. Uniformly accelerated motion; no initial velocity, v_0 .—Problems that come under this head are those in which the body starts from rest and is acted upon by a constant force in the direction of its motion. A train starting from a station, or a body falling from a height, are examples. In the following, friction is neglected:

(a).—ACCELERATION, TIME AND VELOCITY.

$$v = gt; t = \frac{v}{g}; g = \frac{v}{t} = \frac{v_1}{t_1} = \frac{v-v_1}{t-t_1}.$$

Fig. 5.

$$v = at; t = \frac{v}{a}; a = \frac{v}{t} = \frac{v_1}{t_1} = \frac{v-v_1}{t-t_1}.$$

Fig. 6.

Ex. 3.—What velocity will a body acquire at the end of 10 seconds, falling in a vacuum?

$$\text{Ans.} \quad v = gt = 32.2 \times 10 = 322 \text{ ft. per sec.}$$

(b).—TIME, VELOCITY AND DISTANCE.

$$h = \frac{vt}{2}; t = \frac{2h}{v}; v = \frac{2h}{t} = \frac{2(h-h_1)}{t-t_1}.$$

Fig. 7.

$$s = \frac{vt}{2}; t = \frac{2s}{v}; v = \frac{2s}{t} = \frac{2(s-s_1)}{t-t_1}.$$

Fig. 8. Google

Ex. 4.—A body falling in a vacuum attains a velocity of 322 ft. per sec. at the end of 10 seconds. Through what height has it fallen?

Ans.— $h = \frac{vt}{2} = \frac{1}{2} (322 \times 10) = 1610$ ft.

Note that $\frac{v}{2}$ is the *average* velocity for the time t .

(c).—VELOCITY, DISTANCE AND ACCELERATION.

$$g = \frac{v^2}{2h}; h = \frac{v^2}{2g}; v = \sqrt{2gh} = 8.02\sqrt{h}.$$

Fig. 9.

$$a = \frac{v^2}{2s}; s = \frac{v^2}{2a}; v = \sqrt{2as}.$$

Fig. 10.

Ex. 5.—What final velocity will a body acquire in falling 1000 ft. the earth?

Ans.—Final velocity $= v = 8.02\sqrt{h} = 8.02 \times 31.62 = 253.6$ ft. per sec.

(d).—DISTANCE, ACCELERATION AND TIME.

$$t = \sqrt{\frac{2h}{g}} = .249\sqrt{h}; g = \frac{2h}{t^2}; h = \frac{gt^2}{2} = 16.1t^2.$$

Fig. 11.

$$t = \sqrt{\frac{2s}{a}}; a = \frac{2s}{t^2}; s = \frac{at^2}{2}.$$

Fig. 12.

Ex. 6.—Starting from rest, what acceleration per sec. will cause body to travel 2000 ft. in 10 seconds?

Ans.— $a = \frac{2s}{t^2} = \frac{2 \times 2000}{10^2} = 40$ ft. every second.

Note that the term "acceleration" means "rate of acceleration second"—increase in velocity per second.

III. Uniformly accelerated motion with positive initial velocity. This is a case of uniformly varying motion in which the constant initial velocity v_0 is in the same direction as the accelerated velocity v produced by some constant, acting force. Let $V = v + v_0$ = the resultant velocity at time t measured from the instant that v begins to act; h or s = the distance traveled in that time; g or a = the rate of acceleration per second. The following relations exist, neglecting friction:

(A).—ACCELERATION, TIME AND VELOCITY.

$$V = v + v_0 - gt + v_0; v = V - v_0; v_0 = V - gt. \quad \left| \quad V = v + v_0 - at + v_0; v = V - v_0; v_0 = V - at. \right.$$

$$t = \frac{V - v_0}{g} = \frac{v}{g}. \quad g = \frac{V - v_0}{t} = \frac{v}{t}. \quad \left| \quad t = \frac{V - v_0}{a} = \frac{v}{a}. \quad a = \frac{V - v_0}{t} = \frac{v}{t} \right.$$

Ex. 7.—A stone is thrown from a balloon vertically downward toward the earth with a velocity of 100 ft. per sec., striking the earth with a velocity of 1000 ft. per sec. What is the time of its descent?

Ans.— $t = \frac{V - v_0}{g} = \frac{1000 - 100}{32.2} = 28.0$ seconds.

(B).—TIME, VELOCITY AND DISTANCE.

$$h = \frac{t}{2} (V + v_0) = t \left(\frac{v}{2} + v_0 \right); \quad \left| \quad s = \frac{t}{2} (V + v_0) = t \left(\frac{v}{2} + v_0 \right); \right.$$

$$t = \frac{2h}{V + v_0} = \frac{h}{\frac{v}{2} + v_0}. \quad \left| \quad t = \frac{2s}{V + v_0} = \frac{s}{\frac{v}{2} + v_0} \right.$$

$$V = \frac{2h}{t} - v_0; v = 2 \left(\frac{h}{t} - v_0 \right); v_0 = \frac{h}{t} - \frac{v}{2}. \quad \left| \quad V = \frac{2s}{t} - v_0; v = 2 \left(\frac{s}{t} - v_0 \right); v_0 = \frac{s}{t} - \frac{v}{2} \right.$$

Ex. 8.—At what height above the ground is the balloon in Ex. 7, preceding?

Ans.— $h = \frac{t}{2} (V + v_0) = 14 \times 1100 = 15400$ ft.

(C).—VELOCITY, DISTANCE AND ACCELERATION.

$$g = \frac{V^2 - v_0^2}{2h} = \frac{v(v + 2v_0)}{2h} = \frac{v(2V - v)}{2h}. \quad \left| \quad a = \frac{V^2 - v_0^2}{2s} = \frac{v(v + 2v_0)}{2s} = \frac{v(2V - v)}{2s} \right.$$

$$h = \frac{V^2 - v_0^2}{2g} = \frac{v(v + 2v_0)}{2g} = \frac{v(2V - v)}{2g}. \quad \left| \quad s = \frac{V^2 - v_0^2}{2a} = \frac{v(v + 2v_0)}{2a} = \frac{v(2V - v)}{2a} \right.$$

$$V = \sqrt{2gh + v_0^2}; v_0 = \sqrt{V^2 - 2gh}; v = \sqrt{V^2 - 2as}; v_0 = \sqrt{V^2 - 2as}; v = \sqrt{v_0^2 + 2gh} - v_0. \quad \left| \quad V = \sqrt{2as + v_0^2}; v_0 = \sqrt{V^2 - 2as}; v = \sqrt{v_0^2 + 2as} - v_0 \right.$$

Ex. 9.—At a point one mile above the earth's surface a rifle ball is fired downward to the earth with an initial velocity of 2200 ft. per sec. With what velocity does it strike the earth?

Ans.— $V = \sqrt{2gh + v_0^2} = \sqrt{2 \times 32.2 \times 5280 + (2200)^2} = 2276$ ft. per sec.

(D).—DISTANCE, ACCELERATION AND TIME.

$$t = \sqrt{\left(\frac{v_0}{g} \right)^2 + \frac{2h}{g}} - \frac{v_0}{g}. \quad \left| \quad t = \sqrt{\left(\frac{v_0}{a} \right)^2 + \frac{2s}{a}} - \frac{v_0}{a} \right.$$

$$s = \frac{2}{t} \left(\frac{h}{t} - v_0 \right). \quad h = t \left(\frac{gt}{2} + v_0 \right). \quad \left| \quad a = \frac{2}{t} \left(\frac{s}{t} - v_0 \right). \quad s = t \left(\frac{at}{2} + v_0 \right) \right.$$

Ex. 10.—In what length of time will a body travel 2000 ft., if the initial velocity is 20 ft. per sec., and the acceleration 10 ft. per sec.?

Ans.— $t = \sqrt{\left(\frac{v_0}{a} \right)^2 + \frac{2s}{a}} - \frac{v_0}{a} = \sqrt{\left(\frac{20}{10} \right)^2 + \frac{4000}{10}} - \frac{20}{10} = 18.1$ seconds.

IV. Uniformly accelerated motion with negative initial velocity v_0 .—This is a case of uniformly varying motion in which the constant, initial velocity v_0 is *opposite in direction* to the accelerated velocity v produced by some constant, acting force. Let $v' = v - v_0$ = the resultant velocity, in the direction of v at any time t measured from the instant v begins to act; h or s = the distance (algebraic) traveled in that time; g or a = the rate of acceleration per second. Then the following relations exist, neglecting friction:

(A').—ACCELERATION, TIME AND VELOCITY.

$$\begin{aligned} v' &= v - v_0 = gt - v_0; \quad v = gt; \quad v_0 = gt - v'. & \left| \quad v' &= v - v_0 = at - v_0; \quad v = at; \quad v_0 = at - v'. \right. \\ t &= \frac{v' + v_0}{g} = \frac{v}{g}. & \quad g &= \frac{v' + v_0}{t} = \frac{v}{t}. & \left| \quad t &= \frac{v' + v_0}{a} = \frac{v}{a}. \quad a = \frac{v' + v_0}{t} = \frac{v}{t}. \right. \end{aligned}$$

Ex. 11.—From a point distant h (unknown) above the earth, a rock is thrown vertically upward with a velocity of 200 ft. per sec., and in falling strikes the earth with a velocity of 400 ft. per sec. What length of time is the stone in the air?

$$\text{Ans.} \quad t = \frac{v' + v_0}{g} = \frac{400 + 200}{32.2} = 18.63 \text{ seconds.}$$

(B').—TIME, VELOCITY AND DISTANCE.

$$\begin{aligned} h &= \frac{t}{2} (v' + v_0). & \quad t &= \frac{2h}{v' + v_0}. & \left| \quad s &= \frac{t}{2} (v' + v_0). & \quad t &= \frac{2s}{v' + v_0}. \right. \\ v' &= \frac{2h}{t} + v_0; \quad v_0 = v' - \frac{2h}{t}; \quad v = 2 \left(\frac{h}{t} + v_0 \right). & \left| \quad v' &= \frac{2s}{t} + v_0; \quad v_0 = v' - \frac{2s}{t}; \quad v = 2 \left(\frac{s}{t} + v_0 \right). \right. \end{aligned}$$

Ex. 12.—In example 11, preceding, find the distance h of the starting point above the ground?

$$\text{Ans.} \quad h = \frac{t}{2} (v' + v_0) = \frac{18.63}{2} (400 + 200) = 1863 \text{ ft.}$$

Note.—From formulas (c) we find that the rock ascended $h = \frac{v_0^2}{2g} = \frac{(200)^2}{2g} = 621$ ft.; and then descended $h = \frac{v'^2}{2g} = \frac{(400)^2}{2g} = 2484$ ft. See Ex. 13, illustrating this.

(C').—VELOCITY, DISTANCE AND ACCELERATION.

$$\begin{aligned} g &= \frac{v'^2 - v_0^2}{2h}. & \quad h &= \frac{v'^2 - v_0^2}{2g}. & \left| \quad a &= \frac{v'^2 - v_0^2}{2s}. & \quad s &= \frac{v'^2 - v_0^2}{2a}. \right. \\ v' &= \sqrt{2gh + v_0^2}; \quad v_0 = \sqrt{v'^2 - 2gh}. & \left| \quad v' &= \sqrt{2as + v_0^2}; \quad v_0 = \sqrt{v'^2 - 2as}. \right. \end{aligned}$$

Ex. 13.—In Example 11, find the distance h of the starting point above the ground, using the acceleration instead of the time (Ex. 12)?

$$\text{Ans.} \quad h = \frac{v'^2 - v_0^2}{2g} = \frac{(400)^2 - (200)^2}{64.4} = 1863 \text{ ft.}$$

(D').—DISTANCE, ACCELERATION AND TIME.

$$\begin{aligned} t &= \sqrt{\left(\frac{v_0}{g}\right)^2 + \frac{2h}{g}} + \frac{v_0}{g}. & \left| \quad t &= \sqrt{\left(\frac{v_0}{a}\right)^2 + \frac{2s}{a}} + \frac{v_0}{a}. \right. \\ g &= \frac{2}{t} \left(\frac{h}{t} + v_0 \right). & \quad h &= t \left(\frac{gt}{2} - v_0 \right). & \left| \quad a &= \frac{2}{t} \left(\frac{s}{t} + v_0 \right). & \quad s &= t \left(\frac{at}{2} - v_0 \right). \right. \end{aligned}$$

Ex. 14.—In Example 11, find the distance h of the starting point above the ground, using the time, acceleration and initial velocity?

$$\text{Ans.} \quad h = t \left(\frac{gt}{2} - v_0 \right) = 1863 \text{ ft.}$$

1.—FALLING BODIES.*

(h —height of fall; t —time in seconds; v —final veloc. in ft. per sec.)

$$v = gt = 32.16t, \quad t = \frac{v}{g} = .031095 v, \quad h = \frac{v^2}{2g} = .015547 v^2,$$

$$-\sqrt{2gh} = -8.02\sqrt{h}, \quad -\sqrt{\frac{2h}{g}} = -.2494\sqrt{h}, \quad -\frac{g^2}{2} = -16.08 s.$$

* Ex.—A body falling from a height h of 398 ft. reaches the earth in 5 seconds, attaining a final velocity v of 160 ft. per sec. If the body were shot vertically upward with an initial velocity of 160 ft. per sec. it would reach the starting point, 398 ft. above the earth, in 5 sec. Each motion would be just the inverse of the other. See, also, table on page 1165.

SUMMARY OF PRECEDING MOTION FORMULAS.

Notation:

- a = rate of acceleration in feet per second.
 g = gravity acceleration in feet per second.
 v = velocity at time t , in ft. per sec., due to acceleration only.
 v_0 = constant or uniform or initial velocity in ft. per sec.
 V = $v + v_0$ = resultant velocity in ft. per sec. with initial velocity *positive*.
 v' = $v - v_0$ = resultant velocity in ft. per sec. with initial velocity *negative*.
 s = direct distance in ft. from point of starting. (Used with a .)
 h = direct distance in ft. from point of starting. (Used with g .)
 t = time in seconds after starting.

Formulas:

I. Uniform motion; no acceleration.

$$v_0 = \frac{h}{t} = \frac{s}{t}. \quad h = v_0 t; \quad s = v_0 t. \quad t = \frac{h}{v_0} = \frac{s}{v_0}.$$

II. Uniformly accelerated motion; no initial velocity.

$$v = gt = at = \frac{2h}{t} = \frac{2s}{t} = \sqrt{2gh} = \sqrt{2as}. \quad h = \frac{vt}{2} = \frac{v^2}{2g} = \frac{gt^2}{2}; \quad s = \frac{vt}{2} = \frac{v^2}{2a} = \frac{at^2}{2}.$$

$$t = \frac{v}{g} = \frac{v}{a} = \frac{2h}{v} = \frac{2s}{v} = \sqrt{\frac{2h}{g}} = \sqrt{\frac{2s}{a}}. \quad g = \frac{v}{t} = \frac{v^2}{2h} = \frac{2h}{t^2}; \quad a = \frac{v}{t} = \frac{v^2}{2s} = \frac{2s}{t^2}.$$

III. Uniformly accelerated motion; initial velocity positive.

$$V = gt + v_0 = at + v_0 = \frac{2h}{t} + v_0 = \frac{2s}{t} + v_0 = \sqrt{2gh + v_0^2} = \sqrt{2as + v_0^2}.$$

$$v_0 = V - gt = V - at = \frac{h}{t} - \frac{v}{2} = \frac{s}{t} - \frac{v}{2} = \sqrt{V^2 - 2gh} = \sqrt{V^2 - 2as}.$$

$$v = gt = at = 2 \left(\frac{h}{t} - v_0 \right) = 2 \left(\frac{s}{t} - v_0 \right) = \sqrt{v_0^2 + 2gh} - v_0 = \sqrt{v_0^2 + 2as} - v_0.$$

$$h = \frac{t}{2} (V + v_0) = \frac{V^2 - v_0^2}{2g} = t \left(\frac{gt}{2} + v_0 \right); \quad s = \frac{t}{2} (V + v_0) = \frac{V^2 - v_0^2}{2a} = t \left(\frac{at}{2} + v_0 \right).$$

$$g = \frac{v}{t} = \frac{V - v_0}{t} = \frac{V^2 - v_0^2}{2h} = \frac{2}{t} \left(\frac{h}{t} - v_0 \right); \quad a = \frac{v}{t} = \frac{V - v_0}{t} = \frac{V^2 - v_0^2}{2s} = \frac{2}{t} \left(\frac{s}{t} - v_0 \right).$$

IV. Uniformly accelerated motion; initial velocity negative.

$$v' = gt - v_0 = at - v_0 = \frac{2h}{t} + v_0 = \frac{2s}{t} + v_0 = \sqrt{2gh + v_0^2} = \sqrt{2as + v_0^2}.$$

$$v_0 = gt - v' = at - v' = v' - \frac{2h}{t} = v' - \frac{2s}{t} = \sqrt{v'^2 - 2gh} = \sqrt{v'^2 - 2as}.$$

$$v = gt = at = 2 \left(\frac{h}{t} + v_0 \right) = 2 \left(\frac{s}{t} + v_0 \right) = \sqrt{2gh + v_0^2} + v_0 = \sqrt{2as + v_0^2} + v_0.$$

$$g = \frac{v}{t} = \frac{v' + v_0}{t} = \frac{v'^2 - v_0^2}{2h} = \frac{2}{t} \left(\frac{h}{t} + v_0 \right); \quad a = \frac{v}{t} = \frac{v' + v_0}{t} = \frac{v'^2 - v_0^2}{2s} = \frac{2}{t} \left(\frac{s}{t} + v_0 \right).$$

The resultant of two constant velocities in different directions is a motion in a straight line, and may be termed the parallelogram of motions or the triangle of motions. Let v_0' and v_0'' represent two velocities of magnitude and direction shown in Figs. 13 and 14, and making any angle θ with each other. Then will V_0 be the resultant velocity both in magnitude and direction:

Fig. 13.

Fig. 14.

From Trigonometry, $V_0^2 = v_0'^2 + v_0''^2 + 2v_0'v_0'' \cos \theta$;

$$\therefore V_0 = \sqrt{v_0'^2 + v_0''^2 + 2v_0'v_0'' \cos \theta}.$$

Note.—The polygon of motions is analogous to the polygon of forces (see Figs. 31 to 35).

Fig. 15.

Parabolic Motion.—The path of a projectile, or of a jet from a nozzle, illustrates the resultant of a constant velocity v_0 in one direction, and a variable velocity v in another direction. Let x and y (Fig. 15) be the coordinates of any point p in the path of the resultant curve; then

$x = v_0 t \cos \theta$ = horizontal distance traveled;

$y = t \left(v_0 \sin \theta - \frac{gt}{2} \right)$ = vertical distance traveled

$$= x \tan \theta - \frac{gx^2}{2v_0^2 \cos^2 \theta};$$

$\frac{dy}{dx} = \tan \theta - \frac{gx}{v_0^2 \cos^2 \theta}$ = nat tan of angle which the tangent to the curve

makes with the axis of X . Making $\frac{dy}{dx} = 0$, we obtain the coordinates

x' and y' of the point p' at the vertex of the curve; thus,

$$x = x' = \frac{v_0^2 \sin \theta \cos \theta}{g}; \text{ and } y = y' = \frac{v_0^2 \sin^2 \theta}{2g}.$$

When p falls to the point p'' on the axis of X , $y = y' = 0$; and $x = x' = \frac{2v_0^2 \sin \theta \cos \theta}{g}$. $\therefore x'' = 2x'$, or the horizontal distance from o to p'' is double that from o to the vertex p' .

The general equation of the time t occupied in moving from o to any point p is

$$t = \sqrt{\left(\frac{v_0 \sin \theta}{g} \right)^2 - \frac{2y}{g}} + \frac{v_0 \sin \theta}{g}.$$

In moving from o to the vertex p' , (making $y = \frac{v_0^2 \sin^2 \theta}{2g}$),

$$t = \frac{v_0 \sin \theta}{g}.$$

In moving from o to p'' on the axis of X , (making $y = 0$),

$$t = \frac{2v_0 \sin \theta}{g}.$$

The above discussion is a general case of which the following are special cases:

Case 1. Initial velocity horizontal ($\theta = 0$).—

$$x = v_0 t, \quad y = -\frac{gt^2}{2}.$$

Case 2. Initial velocity vertical ($\theta = 90^\circ$).—

$$x = 0, \quad y = t \left(v_0 - \frac{gt}{2} \right).$$

(The last is a case of Uniformly Retarded Motion, being the reverse of "Uniformly Accelerated Motion with negative initial velocity," preceding. Note that y corresponds with h of the preceding Motion formulas; and that when y becomes a minus quantity, p is below the starting point.)

When the value of y is a minus quantity, in any of the above cases, it shows that the projectile p has fallen below the axis of X .

Circular Motion.—Let p be a point on the rim of a fly-wheel of radius r , and revolving at n revolutions per unit of time. Then the velocity v of the point p is

$$v = 2\pi r n.$$

(Note that v takes the compound denomination of r and n ; i.e., if r = rad in *ft.*, and n = rev per *sec.*, then v = *veloc in ft. per sec.*)

Ex. 15.—A driving rope traveling at the rate of 300 ft. per min runs over a pulley 4 ft. in *diam.* How many revolutions does the pulley make per min?

$$\text{Ans.} \quad n = \frac{v}{2\pi r} = \frac{300}{4\pi} = 23.87 \text{ rev per min.} \quad \text{Ans.}$$

Fig. 16.

Motion on Inclined Plane.—Neglecting friction, bodies falling from A would reach a (on inclined plane Aa), b (on inclined plane Ab), and H (distant $2r$ vertically below) in the same length of time t . Thus,

$$\text{from general formula, } t = \sqrt{\frac{2h}{g}} \quad \text{for } AH;$$

$$\text{as } h = \frac{l}{\sin \alpha}, \quad t = \sqrt{\frac{2l}{g \sin \alpha}} \quad \text{for } Aa;$$

$$\text{as } h = \frac{l'}{\sin \beta}, \quad t = \sqrt{\frac{2l'}{g \sin \beta}} \quad \text{for } Ab.$$

Fig. 17.

Moreover, the velocities at the same elevation would be equal; thus, the velocity of the body at a , descending on the inclined plane Aa , would be equal to the velocity of the body at a' , falling freely through space. Similarly, the velocities at b and b' would be equal.

The following formulas relate to the inclined plane Aa , making an angle α with the horizontal:

$$v = gt \sin \alpha = \sqrt{2gl \sin \alpha}. \quad l = \frac{g t^2 \sin \alpha}{2} = \frac{v^2}{2g \sin \alpha}.$$

$$t = \frac{v}{g \sin \alpha} = \sqrt{\frac{2l}{g \sin \alpha}}.$$

The time occupied in the descent of bodies down inclined planes of the same height varies as the length of the planes. Thus, let $A_1a = 2 \times Aa = 2l$; then the time occupied in falling from A_1 to a would be double that occupied in falling from A to a .

Motion on Cycloidal Curve.—The cycloid (Fig. 18) is often called the curve of quickest descent. Let ACB be the cycloidal curve (of length $4d$) generated by a circle of diam d rolled along the plane AB . Then will a body starting at A fall to C and to B quicker than by any other curve. (For Properties of the Cycloid, see page 236.)

Fig. 18.

Time occupied in reaching C :

$$t = \frac{\pi}{2} \sqrt{\frac{2d}{g}} = \frac{1}{2} \sqrt{\frac{2\pi L}{g}}.$$

Time occupied in reaching B :

$$t = \pi \sqrt{\frac{2d}{g}} = \sqrt{\frac{2\pi L}{g}}.$$

By cycloidal curve.

Time occupied in descent from A to C on the inclined plane AC , is
 $t = \sqrt{\frac{2l}{g \sin \alpha}} = 1.862 \sqrt{\frac{2d}{g}}$, as against $t = 1.5708 \sqrt{\frac{2d}{g}}$ for the cycloid. (See also Simple Cycloidal Pendulum, below.)

Simple Circular Pendulum.—This consists of a mass suspended from a fixed point O by a thread, of length l , considered as having no weight. The length of time t for a single vibration from A to B is

$$t = \pi \sqrt{\frac{l}{g}} \left(1 + \frac{h}{8l}\right) \quad (\text{Nearly exact.})$$

$t = \pi \sqrt{\frac{l}{g}}$ (Approximate but most frequently used; practically exact when α does not exceed $2^\circ 30'$).

Fig. 19.

From the second equation we get, $l = \frac{g t^2}{\pi^2}$; $g = \frac{\pi^2 l}{t^2}$. The length of a pendulum which will give a single vibration in 1 second of time is $l = \frac{g}{\pi^2}$ ft. = 0.101321 g ft. The value of g for any locality may be obtained from the formula*—

$$g = 32.16954 (1 - 0.00284 \cos 2\lambda) \left(1 - \frac{2h}{R}\right) \text{ ft. per sec.}$$

in which λ = latitude of the place,

h = its elevation in feet above sea level,

R = radius in feet of the earth at the latitude λ ,

= 20 887 510 (1 + 0.00164 cos 2λ),

= 20 900 000 ft., approximately.

The value of g in England is 32.2 ft.; in New York City, 32.17. The value of g usually assumed in the U. S. is 32.16; and of $\sqrt{2g}$, is 8.02, in hydraulics. The length of a pendulum which will make a single vibration in one second is therefore $l = 0.101321 g = 0.101321 \times 32.16 = 3.258$ ft. = 39.1 ins., or a little less than 1 meter (= 3.28 ft. = 39.37 ins.).

The compound circular pendulum consists of a pendulum in which the mass is more or less distributed, instead of being concentrated at a single point as above (Fig. 19). It may be reduced to the simple circular pendulum by finding the distance l from O to the center of oscillation, otherwise termed the center of percussion. Assuming the whole pendulum to be rigid, the center of percussion is such a point that when struck sharply at right angle to the direction of the pendulum the latter will begin to oscillate or vibrate as a simple pendulum without producing any shock at its upper end or axis O . If the pendulum is a rod of uniform cross-section, and homogeneous, the center of percussion† will be a point distant $l = \frac{1}{3}$ of the length of the rod from O .

Simple Cycloidal Pendulum.—Let Op (= $2d$), Fig. 18, be the length of the pendulum vibrating between the cycloidal arcs OA and OB . Then will Op be the evolute of the cycloid ACB , and the mass p will trace the cycloidal curve. Hence the motion of the mass p will be the same whether it is swinging from O or simply rolling freely on ACB , friction neglected. Moreover, for any given cycloid the time of descent from any point on the

curve will be $t = \pi \sqrt{\frac{d}{g}}$; and the time of one oscillation, $t = \pi \sqrt{\frac{2d}{g}}$. In order

that the time of one oscillation may be one second, make $2d = \frac{g}{\pi^2} = 0.101321$ ft.; $\therefore$ the length of the cycloidal pendulum, = $2d$, will be the same length as the Simple Pendulum, preceding. The cycloidal pendulum is exact for any angle of vibration, while the simple pendulum is practically correct only for small arcs if the formula is adhered to strictly.

DYNAMICS.

Work, Power, Energy, Etc.

Force.—In the preceding equations of motion, the mass of the moving body is not considered—simply abstract motions. When, however, the moving body is considered as having mass, it will take on the conception of *force* (=mass×acceleration), *work* (=force×distance), *power* (=rate of work=work÷time), and *energy* (=capacity for work); also "*impulse*" (=force×time), and "*momentum*" (=mass×velocity),—remembering that the momentum imparted to a body is equal to the impulse which produces it. ("Impact" or "collision" is a blow, or pressure of such short duration that it cannot be measured, between two bodies. See page 303.)

Considering "Force" F to be a constant, unbalanced, resultant for acting on a total mass M of weight W during the time t , the above relations may be summarized as follows:

(a). Fundamental Relations; Resultant Force F Constant.
(Distance not included.)

$$\text{Impulse} = \text{force} \times \text{time} = \text{mass} \times \text{velocity} = \text{momentum} \dots\dots\dots (1)$$

$$\frac{\text{weight} \times \text{velocity}}{g} = \dots\dots\dots (2)$$

Therefore,

$$\begin{aligned} \text{Mass} \quad M &= \frac{Ft}{v} = \frac{F}{a} = \frac{W}{g} \dots\dots\dots (3) \\ (\text{Force-}) \quad \text{Accel} \quad a &= \frac{F}{M} = \frac{Fg}{W} = \frac{v}{t} \text{ in ft. per sec.} \dots\dots\dots (4) \\ \text{Weight} \quad W &= Mg = \frac{Fg}{a} = \frac{Fgt}{v} \text{ in pounds.} \dots\dots\dots (5) \\ (\text{Gravity-}) \quad \text{Accel} \quad g &= \frac{W}{M} = \frac{Wa}{F} = \frac{Wv}{Ft} \text{ in ft. per sec.} \dots\dots\dots (6) \\ \text{Force} \quad F &= \frac{Mv}{t} = \frac{Wa}{g} = \frac{Wv}{gt} \text{ in pounds.} \dots\dots\dots (7) \\ \text{Time} \quad t &= \frac{Mv}{F} = \frac{Wv}{Fg} = \frac{v}{a} \text{ in seconds.} \dots\dots\dots (8) \\ \text{Velocity} \quad v &= \frac{Ft}{M} = \frac{Fgt}{W} = at \text{ in ft. per sec.} \dots\dots\dots (9) \end{aligned}$$

Remarks.—The above formulas are for problems in which the force and therefore acceleration, is constant. Equated values may be substituted from one formula in another.

Problem 1.—A railroad train weighing 600 tons, 5 minutes after starting attains a velocity of 30 miles per hour. Find the tractive force of the engine drawing the train, the resistance being 8 lbs. per ton?

Solution.—Tractive force T = unbalanced force F + resistance

$$\text{From formula (7), } F = \frac{Wv}{gt} = \frac{600 \times 2000 \times 30 \times 5280}{32.16 \times 5 \times 60 \times 3600} = 5473 \text{ lbs.; and } R = 600 \times 8 = 4800 \text{ lbs.; } \therefore T = F + R = 5473 + 4800 = 10273 \text{ lbs. Ans.}$$

ATWOOD'S MACHINE.

Problem 2.—Atwood's machine consists of a flexible cord passing over a (frictionless) pulley and supporting equal weights at each end, with provision for an "unbalanced" weight at either end. In Fig. 20, the balanced weights are 5 lbs., and the unbalanced weight is 2 lbs. Find the acceleration of the weights, and the tension on the cord?

Solution.—From formula (4), acceleration $a = \frac{Fg}{W} = \frac{2 \times 32.2}{12} = 5.37 \text{ ft. per sec.};$ and $\frac{a}{g} = \frac{F}{W} = \frac{2}{12} = \frac{1}{6}$. In considering the tension T on the cord, we have to consider the weight W' whose mass is M' and acceleration a

4; thus, $T = F' + W' = (\text{formula 7}) \frac{W'a}{g} + W' = \frac{10}{6} + 5 =$

Problem 2 corresponds with the resistance R in Prob-

1, the acceleration, and tension assuming no friction? (Note Wood's Machine, Fig. 20.)

acceleration $a = (\text{formula 7}) \frac{Fg}{W} =$

and $\frac{a}{g} = \frac{2}{12} = \frac{1}{6}$. As there is no

resistance, hence the tension Fig. 21.

+ R ($R=0$) = $F' = (\text{formula 7}) \frac{W'a}{g} = \frac{10}{6} = 1\frac{2}{3}$ lbs. Ans.

the total force F ($= 2$ lbs.), $\frac{2}{12}$ or $\frac{1}{6}$ of it is employed in

and the balance or $\frac{5}{6}$ ($= 1\frac{2}{3}$ lbs.) is employed in moving

hence the tension in the rope, as above.)

$$Fs = \frac{Was}{g} = \frac{Wvs}{gt} = \frac{2Ws^2}{gt^2} = \frac{Fvt}{2} = \frac{Fv^2}{2a} = \frac{Fat^2}{2} = Pt =$$

$$\frac{Zat}{2} = \frac{Nv}{2} \quad (=E) \quad \dots \dots \dots (20)$$

$$\text{Power (ft.-lbs.) } P = \frac{K}{t} = \frac{Fs}{t} = \frac{Was}{gt} = \frac{Wvs}{gt^2} = \frac{2Ws^2}{gt^3} = \frac{Fv}{2} = \frac{Fv^2}{2at} = \frac{Fat}{2} = \frac{Za}{2} = \frac{Nv}{2t} \dots\dots\dots (21)$$

$$\text{Energy (ft.-lbs.) } E = \frac{Mv^2}{2} = \frac{Wv^2}{2g} = \frac{Fv^2}{2a} \text{—same values as for } K, \text{ above (} = K \text{)} \quad (22)$$

(Remarks.—The above formulas are for problems in which the force, and therefore acceleration, is constant. Equated values may be substituted from one formula in another.)

Problem 4.—How much energy is expended in raising a weight of 800 lbs., 10 ft.?

Solution.—From formula (20), $E = K = Fs = 800 \times 10 = 8000$ ft.-lbs. of energy or work. **Ans.**

Problem 5.—A weight of 4000 lbs. is raised 100 ft. in 5 seconds. Find the tension in the hoisting rope, the acceleration being uniform? (See Fig. 22.)

Solution.—Tension T = unbalanced force F + the resistance R ($= W$) = (formula 16) $\frac{2Ws}{gt^2} + W = \frac{4000 \times 200}{32.2 \times 25} + 4000 = 994 + 4000 = 4994$ lbs. **Ans.**

Fig. 22.

Work.—Work is the transformation of energy, and is simply force (F) $\times$ distance (s). The foot-pound (one pound raised one foot high, or its equivalent) is generally considered the unit of work unless other units are specified. The element of *time* is not a factor.

The Fundamental Formulas for Work are—

When the force F is constant, $\text{Work } (K) = Fs \dots\dots\dots (23)$

When the force F is uniformly variable, $\text{Work } (K) = \int_{s_0}^{s_1} F ds \dots\dots\dots (24)$

In which s_1 and s_0 are the limiting values of s , in feet.

Problem 6.—A rope weighing 6 lbs. per lin. ft. and 400-ft. long, is suspended at one end from a drum. Find the least number of ft.-lbs. of work required to wind up 100-ft. of it?

Solution.—Let s (Fig. 23) be the variable length of the hanging rope; then $6s$ will be its weight, and $6s ds$ the work done in raising it through the distance ds . Using formula (24), the total work done in raising the rope through 100-ft. of distance is

$$K = \int_{s_0}^{s_1} F ds = \int_{300}^{400} 6s ds = \left[\frac{6s^2}{2} \right]_{300}^{400} = 3(400^2 - 300^2)$$

$= 210\,000$ ft.-lbs. **Ans.**

This is represented graphically in Fig. 24, the vertical ordinate F being the force applied for any length s of the hanging rope, and the shaded area representing the total least work performed. Thus, to wind up the whole rope the least amount of work required would be (making $s_0 = 0$) $\frac{6}{2} \cdot s_1^2 = 3 \times 400^2 = 480\,000$ ft.-lbs. = area whole triangle.

Fig. 23.

Fig. 24.

is the *rate* of work, that is, it is the amount of work done in unit time. It bears the same relation to work that velocity

$$\text{as velocity} = \frac{\text{space traveled}}{\text{time}}.$$

Power may be:

Foot-second unit = 1 lb. raised 1 ft. in 1 sec.

Foot-minute unit = 1 lb. raised 1 ft. in 1 min.

Horse power unit $\left\{ \begin{array}{l} = 550 \text{ foot-pounds per sec.} \\ = 33000 \text{ foot-pounds per min.} \end{array} \right.$

Rate of work per unit of time.

Power, with the force F constant, is—

$$\frac{\text{space}}{\text{time}} = \frac{Fs}{t} \dots \dots \dots (25)$$

A locomotive draws a load of 600 tons at the rate of 20 ft. per sec. resistance being 8 lbs. per ton. Find the horse-power?

$$\frac{Fs}{t} = \frac{8 \times 600 \times 20 \times 5280}{60} \text{ ft.-lbs. per min.}$$

$$= \frac{8 \times 600 \times 20 \times 5280}{60 \times 33000} \text{ horse power.}$$

$$= 256 \text{ h. p. Ans.}$$

Power $\left(\frac{Fs}{t}\right)$ is the rate of work Fs , it is possible through

appliances to accomplish a great amount of work with the same power, by increasing the time t of performing the work. That the ancients understood this is evidenced by the lever, inclined plane, wedge, screw and pulley, in raising weights W , greater than any available direct force F . All problems really come under the principle of *leverage*, simple

Notation.

Force in lbs. applied to first lever,

Distance in ft. that F_1 , or the initial lever end, moves in time t , seconds,

Intermediate forces in lbs. at successive joints of compound lever,

Distances in ft. the intermediate joints move in time t ,

Force in lbs. at end of last lever = weight of mass raised

Distance in ft. that F , or the final lever end, moves in time t .

General Formulas.

$$\text{Example: Power } P = \frac{F_1 s_1}{t} = \frac{Fs}{t}; \text{ Work } K = F_1 s_1 = Fs \dots (26)$$

$$\text{Formulas: Power } P = \frac{F_1 s_1}{t} = \frac{F' s'}{t} = \frac{F'' s''}{t} = \frac{F''' s'''}{t} = \text{etc.} = \frac{Fs}{t} (27)$$

$$\text{Work } K = F_1 s_1 = F' s' = F'' s'' = F''' s''' = \text{etc.} = Fs (28)$$

Formulas neglect friction or loss of energy in the mechanism; assume that the total power and work *applied* to the mechanism is equal to the work *done* into useful work.

The force F_1 raises the weight W (Fig. 26), $F_1 = \frac{W}{\frac{l_1}{l_2}}$ (26), $F_1 = \frac{W l_2}{l_1}$ (26), since $\frac{l_1}{l_2} = \frac{s_1}{s_2}$.

Fig. 25.

Compound Lever.—Let F_1 be the force required to raise W . F_1 and W may be equated with F' acting at the joint of the two levers. Thus,

$$F_1 s_1 = F' s' = F s; \text{ but } s' = \frac{s_1 l_1}{l_1'} = \frac{s l}{l'};$$

$$\therefore \frac{s}{s_1} = \frac{l_1 l'}{l_1' l}; \therefore F_1 = F \frac{s}{s_1} = W \frac{l_1 l'}{l_1' l}.$$

Fig. 26.

Note that the acting force multiplied by the continued product of the *left-hand* lever arms = the weight raised multiplied by the continued product of the *right-hand* lever arms. This principle holds true in belting and gearing also.

Fig. 27.

Inclined Plane.—Let W be a weight to be moved up an inclined plane of length s_1 and height s , by the force F_1 . Then $F_1 s_1 = W s$, or $F_1 = W \frac{s}{s_1}$, in which $\frac{s}{s_1} = \sin \alpha$.

Wedge.—The wedge is a double inclined plane.

Screw.—The screw is an inclined plane wound around a cylinder. The formula $\frac{F_1 s_1}{t} = \frac{F s}{t}$ applies; in which F_1 is the acting force at the end of a lever attached to the screw; s_1 = distance traversed by the lever end in the time t ; F = the force acted against by the screw; and s the progressive distance traversed by the screw in the time t . Or, we may use the formulas

$$F_1 \sqrt{(2\pi l)^2 + \left(\frac{2pl}{d}\right)^2} = Fp \quad (\text{Exact}) \dots \dots \dots (20)$$

$$F_1 (2\pi l) = Fp \quad (\text{Approx.}) \dots \dots \dots (30)$$

in which l = length of lever from *cen* of screw to applied force F_1 , and p = pitch of screw, of *diam* d .

Pulley.—From formula (26), $F_1 s_1 = W s$, in which W moves the distance s when F_1 moves the distance s_1 . In Fig. 28 it is evident that $s_1 = 2s$; hence,

$$F_1 = W \frac{s}{s_1} = \frac{W}{2}.$$

Another method of determining the forces in pulley ropes is by "cutting sections." Thus, imagine all the forces to be in equilibrium, and draw a cutting plane ab . Then it follows that each of the two ropes cut, supports half the weight W , and the cutting plane cd shows that F_1 has the same stress $\frac{W}{2}$.

Fig. 28.

Simple and compound pulleys are thus often more easily analyzed by the "method of sections," although the principle of "work" applies universally.

Toggle.—If the weight W is raised by the force F_1 , use formula (26); thus, $F_1 s_1 = Ws$, or $F_1 = W \frac{s}{s_1} = W \frac{2b}{h}$. (It is to be noted that the required force F_1 gradually decreases as b decreases, and that an almost infinite force W may be raised by a finite force F_1 when b approaches zero.)

Proof: Let F_1 force the toggle joint to the right the infinitesimal distance s_1 ; then W will be raised the infinitesimal distance s , that is, $\frac{s}{2}$ for each lever arm l . Now as l remains constant, we have, before the movement,

$l^2 = b^2 + h^2$; and after the movement, $l^2 = (b - s_1)^2 + \left(h + \frac{s}{2}\right)^2$. Equating, $b^2 + h^2 = b^2 - 2bs_1 + s_1^2 + h^2 + hs + \frac{s^2}{4}$. Remembering that the infinitesimal quantities s_1^2 and $\frac{s^2}{4} = 0$, this reduces to $hs = 2bs_1$, or $\frac{s}{s_1} = \frac{2b}{h}$. The same result may be obtained by the parallelogram of forces indicated in Fig. 29.

Fig. 29.

Impulse and Momentum.—If a constant force F acts for a length of time t on a Mass M , the latter will acquire a velocity v at the end of that time. Furthermore, the product Ft , called *impulse*, is equal to the product Mv , called *momentum*; or

$$(Impulse, Z-) Ft = Mv. \quad (-Momentum, N).$$

The acting force F (lbs.) may be any amount acting through any length of time t (sec.), or it may be a force t -times as large as F acting for one second on the mass; in either case the velocity v of the mass at the end of that time (t seconds in the first case and *one* second in the last case) will be the same, and therefore the momentum will be the same. Hence the momentum of a mass $M \left(-\frac{W}{g}\right)$ moving with a velocity v is equal to that force which in one second will give it that velocity; or, inversely, the amount of force which in one second will bring it to rest.

If the acting force is uniformly variable instead of constant, we have the equation

$$\int Mdv = \int Fdt \quad \text{or} \quad M(v_1 - v_0) = \int_{t_0}^{t_1} Fdt$$

in which v_0 = the velocity when t equals t_0 ,

and v_1 = the velocity when t equals t_1 .

Energy.—Energy is capacity for work. The energy of a body is measured by the amount of work which it is capable of performing, called *potential energy*; or by the amount of work it does perform, called *kinetic energy*.

For illustration, a cannon ball weighing 60 lbs. is raised from A to B , a distance of 20 feet. The work performed in raising it is, therefore, $\int Fds = Fs = 60 \times 20 = 1200$

ft.-lbs. The ball at B may now be considered to possess, by virtue of its position with reference to A , a potential (or statical) energy equivalent to 1200 ft.-lbs.; and which, if the ball is allowed to fall back to A , will be entirely expended in the form of kinetic (or actual) energy when it reaches A and its velocity is destroyed.

Fig. 30.

From the preceding equation, $\int F dt = \int M dv$, multiplying both of the equation by v , and remembering that $v dt = ds$, there is obtained,

Work in ascent stored up at B as potential energy = $\left\{ \int F ds = \int_{\text{at } B}^{\text{at } A} M v dv \right\} \left\{ \begin{array}{l} \text{= Kinetic energy in descent expended at } A \end{array} \right.$

Or, the general formula, $\int F ds = \frac{1}{2} M (v_1^2 - v_0^2)$

If the initial velocity $v_0 = 0$, then $v_1 = v$ and we have,

$$\text{Energy } E = \frac{1}{2} M v^2 = \frac{W v^2}{2g} \dots\dots\dots$$

Or, as $h = \frac{v^2}{2g}$ (IIc), $E = W h = F s = \text{work } K \dots\dots\dots$

That is, the energy expended = the work performed.

Problem 8.—How much energy is expended in shooting a cannon weighing 50 lbs. with an initial velocity of 2300 ft. per sec?

Solution.—From formula (32) energy in ft.-lbs. = $\frac{W v^2}{2g} = \frac{50 \times 52900}{2 \times 32.1}$

4,112,250 ft.-lbs. Ans.

If fired vertically it would ascend, from formula (19),

$$h = \frac{E}{F} = \frac{E}{W} = \frac{4\,112\,250}{50} = 82\,245 \text{ ft.}$$

RESULTANT FORCES.

Composition and Resolution of Forces.—On page 284 are explained parallelogram and triangle of uniform motions composed of two constant initial velocities v_0' and v_0'' , producing the resultant initial velocity V_0 . From Mechanics we learn that: *Forces are proportional to the velocities which they will impart to a given body in a unit of time.* Hence, if F_1 impart velocity v_0' , and F_2 a velocity v_0'' , then will R , the resultant of F_1 and F_2 , the resultant of v_0' and v_0'' (Figs. 13 and 14) of the parallelogram or triangle of motions. Thus, Fig. 31,

$$R^2 = F_1^2 + F_2^2 + 2 F_1 F_2 \cos \theta,$$

$$\text{or } R = \sqrt{F_1^2 + F_2^2 + 2 F_1 F_2 \cos \theta}.$$

When $\theta = 90^\circ$, $\cos \theta = 0$, and

$$R = \sqrt{F_1^2 + F_2^2}.$$

Fig. 31.

Fig. 32.

Fig. 33.

Equilibrium.—If, in Fig 32, the resultant R , of the two forces F_1 and F_2 , is replaced by a third force F_3 equal in magnitude and opposite direction to R , then will the triangle represent a closed triangle of forces, or forces which if allowed to act at any common point P (Fig. 33) will be in equilibrium. Clearly, any one of the forces of a closed angle of forces is equal and opposite to the resultant of the other two

Fig. 34.

Fig. 35.

Polygon of Forces.—It is evident, from the preceding demonstration, that any number of forces as F_1, F_2, F_3, F_4 , and F_5 , acting in equilibrium at a common point P , Fig. 34, will, if drawn consecutively in rotation in the direction of the forces, form a closed polygon of forces, Fig. 35. For any polygon may be cut into triangles by the diagonal lines R_1, R_2 , etc., each diagonal being the resultant of two other forces, and considered as replacing them. Thus R_1 replaces F_1 and F_2 so that we may consider only four forces acting, namely, R_1, F_3, F_4 , and F_5 ; again, R_2 replaces R_1 ($=F_1$ and F_2) and F_3 so only three forces remain, namely, R_2, F_4 and F_5 —a triangle of forces. Hence, as R_2, F_4 and F_5 are in equilibrium, so are all the forces composing the sides of the polygon in equilibrium. The principle of the force polygon, representing static equilibrium of forces, is fundamental to *Graphical Statics*, in the determination of stresses in structures.

Moments and Reactions.—Let AB be a horizontal lever 50-ft. long, fixed at, and free to rotate around, its left hand end A (Fig. 36). If now a weight $W=60\text{ lbs}$ is applied vertically downward at a point $33\frac{1}{3}$ -ft. distant from A , tending to cause the rod to rotate around A in a right hand motion, it is evident that some force R_2 applied at the other end B of the lever will preserve equilibrium or prevent rotation. The value of R_2 is obtained by taking moments M about A , as origin; thus,

$\Sigma M=0: 33\frac{1}{3} W=50 R_2; \therefore R_2=\frac{1}{2} W=40\text{ lbs}$.

In a similar manner, if the lever is considered as fixed at, and free to rotate around, B (Fig. 37), we have $\Sigma M=0: 16\frac{2}{3} W=50 R_1; \therefore R_1=\frac{1}{2} W=20\text{ lbs}$.

Fig. 38 is the combined result of the two operations above, considering the lever AB as a beam 50-ft. long supporting the weight $W=60\text{ lbs}$, producing a reaction of 20 lbs at A and 40 lbs at B . The weight of the beam itself is not considered.

Center of Gravity and Resultant of a System of Parallel Forces.—The line of the resultant of a system of parallel forces passes through the *center of gravity* of the system. In Fig. 39, let P_1 ($=10\text{ lbs}$), P_2 ($=20\text{ lbs}$) and P_3 ($=30\text{ lbs}$) be a system of parallel forces or loads acting on a rigid body AB , at points 25 ft. apart. Then will R ($=60\text{ lbs}$) acting at the point O , be the resultant of the above forces and capable of replacing them in certain problems where the reactions are to be determined. In Alligation, page 57, we have a similar problem, that is, finding the average cost of a

Fig. 36.

Fig. 37.

Fig. 38.

Fig. 39.

mixture where barrels of cement replace pounds, and cents replace of the present problem; and in which the *origin of moments* is 200 ft. left of A. As a matter of fact, the origin of moments may be at any point, but for convenience it will be assumed at A in the present case. Taking moments about A, of the loads P_1 , P_2 and P_3 , we have—

Distance to center of gravity of resultant $= x_0 = \frac{\sum Px}{\sum P}$;

$\sum Px$ = sum of moments of all the forces about center of moments A;

$\sum P$ = sum of all the forces acting $= R$; whence,

$$x_0 = \frac{\sum Px}{\sum P} = \frac{\sum M}{R}; \quad \sum M = x_0 R; \quad R = \frac{\sum M}{x_0}.$$

Taking moments about A as origin:

	$\sum M$	
P_1	$10 \times 0 =$	0
P_2	$20 \times 25 =$	500
P_3	$30 \times 50 =$	1500
$P_1 + P_2 + P_3$	$= 60$	$\frac{\sum M}{R}$
R	$\sum P \times x_0 =$	$\sum M$

Therefore, $R = 60$ lbs.; and $x_0 = \frac{\sum M}{\sum P} = \frac{2000}{60} = 33\frac{1}{3}$ ft.

Note the similarity of analysis of this problem of concentrated forces to the following problem of a distributed force.

Resultant of a Distributed Force.—The resultant of a distributed force is equal to the total force, acting in a line passing through its center of gravity. We have seen (Fig. 39), that the horizontal distance x_0 to the line of the resultant of any system of forces, from any point taken as the origin of moments, is equal to the sum of the moments of the forces about that point, divided by the sum of the forces. The same principle holds true with a distributed force as with a system of forces or concentrated loads.

Fig. 40.

Problem 9.—Let AB, Fig. 40, be a girder of 60 ft. span, s , loaded with distributed force whose intensity, at any point distant x from the left abutment, is the ordinate y from the line AB to the line AC; that is, the intensity of the force increases uniformly from 0 lbs. at A, to 100 lbs. per lin.

at B, so that $y = \frac{100x}{s}$ lbs. 1st, find the general equation of the resultant and its distance x_0 from the left abutment A; 2nd, find R and x_0 for the span completely loaded from A to B; 3rd, find R and x_0 for the span loaded from $b = 20'$ to $a = 50'$.

Solution.—1st. $x_0 = \frac{\sum Px}{\sum P} = \frac{\text{summation of } x \cdot y dx \text{ forces}}{\text{summation of } y dx \text{ forces}} = \frac{\sum M}{R}$.

$$x_0 = \frac{\int_b^a x \left(\frac{100x}{s} \right) dx}{\int_b^a \frac{100x}{s} dx} = \frac{\frac{100}{s} \int_b^a x^2 dx}{\frac{100}{s} \int_b^a x dx} = \frac{\frac{100}{s} \left[\frac{x^3}{3} \right]_b^a}{\frac{100}{s} \left[\frac{x^2}{2} \right]_b^a} = \frac{\frac{100}{s} \left(\frac{a^3 - b^3}{3} \right)}{\frac{100}{s} \left(\frac{a^2 - b^2}{2} \right)} = \frac{2}{3} \times \frac{a^3 - b^3}{a^2 - b^2}$$

In which $\frac{a^3 - b^3}{3} \times \frac{100}{s}$ = sum of the moments of all the infinitesimal $xy dx = \sum M$;

$\frac{a^2 - b^2}{2} \times \frac{100}{s}$ = sum of all the infinitesimal forces $y dx = R$;

$\frac{2}{3} \times \frac{a^3 - b^3}{a^2 - b^2}$ = distance from A to center of gravity of the infinitesimal forces $= x_0$;

a = upper limit of any assigned value to x ;

b = lower limit of any assigned value to x .

2nd. For the span completely loaded from A to B , the upper limit of $x=a=60'$, and the lower limit of $x=b=0$. Substituting these values in the general equation, we have,

$$R = \frac{a^2 - b^2}{2} \times \frac{100}{s} = \frac{3600 - 0}{2} \times \frac{100}{60} = 3000 \text{ lbs.}; x_0 = \frac{1}{3} \cdot \frac{a^3 - b^3}{a^2 - b^2} = \frac{1}{3} a = 40 \text{ ft.}$$

3rd. For a span loaded between $x=a=50'$, and $x=b=20'$, we have,

$$R = \frac{a^2 - b^2}{2} \times \frac{100}{s} = \frac{2500 - 400}{2} \times \frac{100}{60} = 1750 \text{ lbs.}; x_0 = \frac{1}{3} \cdot \frac{a^3 - b^3}{a^2 - b^2} = \frac{1}{3} \cdot \frac{117000}{2100} = 37\frac{1}{3} \text{ ft.}$$

In the same manner we may find the resultant and center of gravity of any distributed force, as parabolic, circular, elliptical, etc., by substituting the value of y in the equation of the curve before summing up all the moments of the ydx forces for $\Sigma Px = \Sigma M$, and all the ydx forces for $\Sigma P = R$. Note that the resultant R —the area of the curve, and the distance x_0 —the distance to its center of gravity.

Centrifugal Force.—Centrifugal force is that component of a force acting radially outward when a body moves along a curve with a certain velocity. In the general equation (16) of force, $F = Ma$, the acceleration

a in the present instance is $\frac{v^2}{r}$ in which v —velocity of the moving body in feet per second, and r —radius of curve in feet. Hence,

$$\text{Centrifugal force} = F = M \frac{v^2}{r} = \frac{W}{g} \cdot \frac{v^2}{r} \dots \dots \dots (34)$$

Problem 10.—Find the tension in a string 10 ft. long, fixed at one end, with a weight of 40 lbs. fastened at the other and revolving around a circle, with the string as a radius, at a velocity of 30 revolutions per minute?

Solution.—In formula (34) F , is the tension in lbs. in the string; and v , in feet per second, is $\frac{30}{60} \cdot 2\pi r$, or $v^2 = \pi^2 r^2$.

$$\begin{aligned} \text{Therefore, tension, } F &= \frac{40}{32.16} \cdot \pi^2 r \\ &= \frac{40 \times 9.87 \times 10}{32.16} = 122.8 \text{ lbs.} \end{aligned}$$

Note that in the above case, F , is a concentrated resultant force acting normal to the curve at one point, and r (=radius of curve) is the distance from center of curve to cen of grav of moving body. Compare above problem with the two following.

Problem 11.—Find the radial pressure which a train weighing 1000 tons and moving 20 miles per hour, will produce on a track laid on a 7 degree curve.

Solution.—The radius of a 7° curve is 819 ft. Use formula (34):

$$\begin{aligned} F &= \frac{W}{g} \cdot \frac{v^2}{r} = \frac{1000 \times \left(\frac{20 \times 5280}{60 \times 60} \right)^2}{32.2 \times 819} \text{ tons} \\ &= 32.63 \text{ tons} = 65300 \text{ lbs.} \text{ Ans.} \end{aligned}$$

Note that in the above case the force F , is a distributed force acting normal to the curve, throughout the length of the train.

Problem 12.—Given a ring (Fig. 41) 4 ft. in diameter, weighing 100 lbs., and revolving about its axis at a speed of 1000 revolutions per minute. Find the tension stress in the ring?

Solution.—[Note.—Distance of center of gravity of the semi-circular ring from center of circle = $r_0 = \frac{2r}{\pi} = \frac{2 \text{ Diam}}{\pi} = \frac{4}{\pi}$ (see page 207).]

Digitized by Google

Consider half the weight of the ring acting at each center of gravity of the semi-circle on the axis of X , causing tension at points a and b on the axis of Y . Then the total stress at a and b , from formula (34) is

$$F_c = \frac{W_1}{g} \cdot \frac{v_0^2}{r_0} \quad \text{in which} \quad \begin{cases} W_1 = 50 \\ v_0 = 2\pi r_0 n = 430 \\ (n = \text{revolutions per second} = 1\frac{1}{3}) \end{cases}$$

$$= \frac{50}{32.2} \cdot \frac{400 \times 400 \times \pi}{8 \times 8 \times 4} = 21690 \text{ lbs.}$$

$\therefore \frac{1}{2} F_c = 10845 \text{ lbs.} = \text{tension at } a \text{ or } b, \text{ or at any point. Ans.}$

Problem 13.—Prove that in order for a train to press normally upon the track in going around a curve of radius r (feet), the outer rail must be

$$\text{elevated an amount } e = \frac{G v^2}{g r} = \frac{G v^2}{32.2 r} \dots\dots\dots (35)$$

in which e = elevation of outer rail in feet,
 v = velocity of train in feet per second,
 G = gauge of track in feet,
 r = radius of curve in feet.

Solution.—The train is exerting two component forces, one horizontally due to centrifugal force and the other vertically due to gravitation, which can be reduced to one resultant force acting normal to the calculated inclined surface of elevated track. In Fig. 42 let e_1 represent intensity of centrifugal force, and $G_1 = W$ = weight of train; then $a_1 b_1$ is the resultant pressure which, in order to be normal to the track, must be at right angle to ab , G being the gauge (practically) and e the required elevation.

Fig. 42.

Through similar triangles, $\frac{e}{e_1} = \frac{G}{G_1}$; but from formula (34), $e_1 = F_c = \frac{W}{g} \frac{v^2}{r}$ and $G_1 = W$,

$$\therefore e = \frac{G e_1}{G_1} = \frac{G \frac{W v^2}{g r}}{W}$$

$$\therefore e = \frac{G v^2}{g r} = \frac{G v^2}{32.2 r} \quad \text{Required proof.}$$

Whence, elevation outer rail = $\frac{\text{gauge of track} \times (\text{velocity of train})^2}{32.2 \times \text{radius of curve in feet}}$.

MOMENTS OF INERTIA, ETC., OF PLANE SURFACES.

Bending Moment—Resisting Moment.—We will now consider the relation between the *moments of the outer forces* of a girder and the *moments of the inner forces*. For example, let Fig. 43 represent a wooden beam 4' wide, 6" deep and 10' long between supports, and loaded uniformly with 120 lbs per lin. ft. Consider the bending moment (of outer forces) and resisting moment (of inner forces) about the center of moments o , situated at the center of the span on the neutral axis $X-X$ of the beam. Then from the nature of the loading,

Fig. 43.

$R_1 = P_1 = P_2 = R_2 = \frac{1}{2}$ total load = $\frac{10 \times 120}{2} = 600 \text{ lbs.}$; P_1 and P_2 each being the resultant of half the total load; R_1 and R_2 the reactions at the points of support. Taking moments of the outer forces to the left of the section at o , we have—

Bending moment = $M_b = R_1 \times 5 - P_1 \times 2\frac{1}{2} = 1500 \text{ ft.-lbs.} = 18000 \text{ inch.-lbs.}$

9000 inch-lbs. must of course be resisted by the moment acting on the right of the vertical section $s-s'$ passing through the beam at $s-s'$; F_c the compressive forces of the section above the neutral axis; and F_t the tensile forces acting to the right on below the neutral axis. As the neutral axis is the center of gravity of the section, will $F_c = F_t$ and the moments about o , we

Fig. 44.

$M_R = 2 F y_0 = M_R = 18000$ inch-lbs., whence $F = \frac{9000}{y_0}$ lbs.

The resultant of a distributed force varying in intensity from the center of the section to f_c at the top and f_t at the bottom is so that the stress in any fiber is directly proportional to the distance from the neutral axis; hence, $f_c = f_t = f$ the intensity of outer fiber stress in lb. per sq. in.; and the resultant forces F_c and F_t act in a line passing through the center of gravity of each distributed force (see Fig. 40), and at a distance from the neutral axis of the beam to the outer fiber;

As the beam is 4 inches wide, we have $F = \frac{f}{2} \cdot \frac{bd}{2} = 4 \times 3$

(see above), or $f = 750$ lbs per sq. in. That is, the maximum

fiber stress on the beam is 750 lbs. per sq. in. (See also (36a) for the ordinary methods of finding the maximum

Moment = Moment of Inertia $\times \frac{f}{y} = \frac{fI}{y}$.—The general formula for the resistance of a beam of any section, is

$$\frac{M y}{I} = f \quad (36)$$

where f is the fiber stress per square inch,

y is the distance in inches from neutral axis to outer fiber,

I is the moment of inertia of section, about the neutral axis.

For a beam of breadth b and depth d , $I = \frac{bd^3}{12}$ and $y = \frac{d}{2}$; hence,

$$M_R = \frac{1}{2} f b d^2; f = \frac{6 M_R}{b d^2}; b = \frac{6 M_R}{f d^2}; d = \sqrt{\frac{6 M_R}{f b}} \quad (36a)$$

which agrees with the preceding analysis, Fig. 44.

Moment of Inertia* = Area $\times$ (radius of gyration)², about an axis in the plane of the surface as bh , resting on the axis of the products of the areas of strips $x dy$ by the squares of their distance from the axis. Thus, for the rectangle of breadth b and height h , where $x = b$, and y varies from $y = 0$, we have, for beam of height h ,

$$I_b = \int_0^h b y^2 dy = \left[\frac{b y^3}{3} \right]_0^h = \frac{b h^3}{3} \quad (37)$$

Fig. 45.

For the moment of inertia of plane figures, see Properties and Tables, Section 29; also, see Properties and Tables of Steel Shapes.

If now another similar and equal rectangle is added *below* the axis of X , making the total height $2h=d$, it is evident that the above moment of inertia will be doubled; thus (Fig. 45),

$$\text{for a beam of depth } d, \quad I_2 = 2I_1 = \frac{1}{3}bh^3 = \frac{bd^3}{12} \dots \dots \dots (38)$$

the general formula for I of a rectangular beam, of depth d , about its neutral axis.

Moment of Inertia about a Parallel Axis.—Let I be the moment of inertia about an axis X passing through the *cen. of grav.* of the plane figure; I' , the moment of inertia about a *parallel axis* X' , distant a from X ; and A , the area of the plane figure; then will

$$I' = I + Aa^2.$$

Moment of Inertia about an Inclined Axis.—See Properties and Tables of Plane Surfaces, Section 29.

$$\text{Radius of Gyration} = \sqrt{\frac{\text{Moment of Inertia}}{\text{Area}}} = \sqrt{\frac{I}{A}}. \text{—The radius of gyration } r \text{ of a plane surface as } bh, \text{ where moment of inertia is } I_1, \text{ and area } A_1, \text{ is the distance } r = y_1, \text{ from the axis of } X \text{ to a point (or line) at which if the whole area were concentrated the moment of inertia would remain the same.}$$

From the above and equation (37) we have, since $I_1 = \frac{bh^3}{3}$ and $A_1 = bh$,

Fig. 46.

$$r = \sqrt{\frac{I_1}{A_1}} = \sqrt{\frac{bh^3}{3} + bh} = \frac{h}{\sqrt{3}} = \frac{h\sqrt{3}}{3} = .577h \dots \dots \dots (39)$$

And for a beam of depth $d = 2h$, with axis through *cen. of grav.*, equation (38),

$$r = \sqrt{\frac{I_2}{A_2}} = \sqrt{\frac{bd^3}{12} + bd} = \frac{d}{\sqrt{12}} = \frac{d\sqrt{3}}{2 \times 3} = \frac{.577d}{2} = .577h \dots \dots \dots (39a)$$

In other words, the radius of gyration r is the same for a rectangle bh resting on the axis of X , as it is for a rectangle bd (in which $d = 2h$) about its neutral axis passing through the center of the section.

Caution.—The radius of gyration r ($=y_1$), Fig. 46, must not be confused with the distance y_0 , Fig. 44, for—

r = distance from axis of X to *cen. of grav. of moment-areas*, while y_0 = *moment-forces*.

In the rectangle bd which, for simplicity, has been referred to throughout the discussion,

$$y_0 = \frac{M}{2F} = \frac{\frac{fI}{y}}{bdf} = \frac{2I}{bdy} = \frac{\frac{12}{bd^2}}{\frac{2}{d}} = \frac{d}{3} = \frac{1}{3}h; \quad \therefore y_0 = \frac{2\sqrt{3}}{3}r = 1.155r \quad (40)$$

$$r = \sqrt{\frac{My}{fA}} = \sqrt{\frac{I}{A}} = \sqrt{\frac{I}{bd}} = \sqrt{\frac{bd^2}{12bd}} = \frac{d}{\sqrt{12}} = \frac{\sqrt{3}}{3}h; \quad \therefore r = \frac{\sqrt{3}}{2}y_0 = .866y_0 \quad (41)$$

$$\text{whence, } y_0^2 = \frac{4}{3}r^2 = \frac{d^2}{9} = \frac{4}{9}h^2; \quad \text{and } r^2 = \frac{3}{4}y_0^2 = \frac{d^2}{12} = \frac{h^2}{3} \dots \dots \dots (42)$$

For other sections than rectangular, these ratios will not hold, necessarily.

Problem 14.—Find the moment of inertia I and radius of gyration r of a circular section (complete circle) of diameter D , about its diameter.

Solution.—The moment of inertia of a complete circle is 4 times that of the quadrant, Fig. 47; and

I of the quadrant equals $I_1 = \int_0^R y^2 x dy$, because xdy is the area of each infinitesimal strip, and y^2 is the

Fig. 47.

tance from the axis of X . From the equation of the circle, $x = \sqrt{R^2 - y^2}$. Substituting this value of x in the above and integrating by formula V of Integral Calculus, page 275,

$$\begin{aligned} \int y^2 dy &= \left[\frac{R}{8} (2y^2 - R^2) \sqrt{R^2 - y^2} + \frac{R^4}{8} \sin^{-1} \frac{y}{R} \right]_0^R \\ &= \frac{R^4}{8} \sin^{-1} 1; \text{ but anti-sine of } 1 = 90^\circ = \frac{\pi}{2}, \\ \therefore I_x &= \frac{\pi R^4}{16}; \\ \therefore 4 I_x &= \frac{\pi R^4}{4}; \end{aligned} \left. \begin{array}{l} \\ \\ \end{array} \right\} = \text{moment of inertia of the circle} \dots (43)$$

$$\therefore I = \frac{\pi D^4}{64}.$$

$$\text{radius } r = \sqrt{\frac{I}{A}} = \sqrt{\frac{\pi D^4}{64} \div \frac{\pi D^2}{4}} = \frac{D}{4} = \frac{R}{2} \dots \dots \dots (44)$$

Rectangular and Circular Beams Compared.—The general resistance of a beam is $M = \frac{f I}{y}$; or $\frac{M}{f} = \frac{I}{y}$. * Now if two beams of equal loading are to have the same *safe resistance* in their outer fiber stresses f , as well as their resisting moments M respectively equal. It remains then simply to equate the section moduli of the two beams. Thus—

For a beam of breadth b and depth d , $\frac{I}{y} = \frac{bd^2}{6}$.

For a beam of diameter D , $\frac{I}{y} = \frac{\pi D^4}{64} \div \frac{D}{2} = \frac{\pi D^3}{32}$.

Equating the values of $\frac{I}{y}$, we have $\frac{\pi D^3}{32} = \frac{bd^2}{6}$.

For a beam of diameter D , $D = 2 \sqrt[3]{\frac{2 b d^2}{3 \pi}}$.

For a beam of depth d , $d = \frac{1}{2} \sqrt[3]{\frac{3 \pi D^3}{b}}$.

For a beam of breadth b , $b = \frac{3 \pi D^3}{16 d^2}$.

A beam of $6\frac{1}{4}$ ins. *diam* will give the same safe resistance as a beam 4" wide and 6" deep, Fig. 44.

Centroid.—The distance to the center of gravity of any plane figure about an axis, is equal to the sum of the moments of each infinitesimal figure about that axis, divided by the total area of the figure.

$$\text{Distance } X_1, \text{ distance } y_0 = \frac{\int x y dy}{\int x dy} \dots \dots \dots (45)$$

its value from the equation of the figure;

$$\text{Distance } Y_1, \text{ distance } x_0 = \frac{\int y x dx}{\int y dx} \dots \dots \dots (46)$$

its value from the equation of the figure.

The *section modulus*, and is equal to the moment of inertia divided by the distance of the most extreme fiber from the neutral axis. See pp. 39 and 40.

It is not necessary, however, to find the moments of *infinitesimal* areas; in fact, the figure may be divided into any number of areas of such shape that their centers of gravity are easily determined. Then the distance from the fixed axis to the center of gravity of the plane figure, is equal to the sum of the products of each area into the distance of its center of gravity from that axis, and this divided by the total area of the figure. Furthermore, the areas whose moments are thus obtained may form one plane figure or any number of plane figures. In the latter case, the center of gravity obtained would be the center of gravity of all the figures. The *exact point* of the center of gravity is determined from *two* coordinate axes.

The center of gravity of a plane figure or system of plane figures or areas, connected or isolated, is the position of the resultant of a uniformly distributed force over the figure or areas; hence a thin sheet, of any outline, may be balanced on a point of support applied at its center of gravity.

MOMENTS OF INERTIA, ETC., OF SOLIDS.

Moment of Inertia.—The moment of inertia of a solid body, about a fixed axis, is the sum of the products of the weight of each infinitesimal particle of matter (composing the body) into the square of its distance from said axis. Hence, the moment of inertia is obtained by the use of the Integral Calculus. An approximation to exact values may be obtained by assuming a *definite* number of *very small* particles, multiplying the weight of each by the square of the distance from its center of gravity to said axis, and finding the sum of these products.

For an axis X passing through the *cen* of *grav* of the body, the moment of inertia $I = \sum wr^2$; where w = the weight of each element, and r = its dist from the axis X .

For an axis X' parallel with and distant d from X , the moment of inertia $I' = I + Wd^2$; where W = the total weight of the body. Hence, knowing the value of I , about an axis passing through the *cen* of *gravity*, the value of I' , about any axis parallel with it can easily be obtained.

2.—MOMENT OF INERTIA OF REGULAR SOLIDS.

Description.	About axis X through c. of g.	About axis X' dist d from X
Sphere of total weight W , and radius r	$\frac{2}{5}Wr^2$	$W\left(\frac{2}{5}r^2 + d^2\right)$
Circular plate of rad r ; axis perp to plate ..	$\frac{Wr^2}{2}$	$W\left(\frac{r^2}{2} + d^2\right)$
Circular cylinder of length $2l$, and ra- dius r	Axis longitudinal...	$W\left(\frac{r^2}{2} + d^2\right)$
	Axis perp to axis of cylind.....	$W\left(\frac{l^2}{3} + \frac{r^2}{4} + d^2\right)$
Circular ring, outerrad r , inner rad r_1 ; axis perp	$W\left(\frac{r^2 - r_1^2}{2}\right)$	$W\left(\frac{r^2 - r_1^2}{2} + d^2\right)$
Rod or bar of uniform cross-section and length $2l$; axis perp to length of rod.....	$\frac{Wl^2}{3}$	$W\left(\frac{l^2}{3} + d^2\right)$

Radius of Gyration.—The radius of gyration of a solid about a fixed axis, is the square root of the quotient obtained by dividing the moment of inertia about that axis, by the total weight of the body. Thus, from Table 2, above, the radius of gyration of a circular plate about a *perp* axis

through its center = $\sqrt{\frac{Wr^2}{2} + W} = \frac{r}{\sqrt{2}} = \frac{r\sqrt{2}}{2}$.

The radius of gyration of a body is the distance from the axis to the center of gyration or point at which if the whole mass were concentrated the moment of inertia would remain the same.

Center of Gravity.—The distance to the center of gravity of any body from a fixed plane, is equal to the sum of the moments of the weight of each infinitesimal particle of matter of the body into its *perp* distance from that plane, divided by the weight of the body.

It is not necessary, however, to find the moments of *infinitesimal* particles; in fact, the body may be divided into any number of parts of such shape that their centers of gravity are easily determined. Then the distance from the fixed plane to the center of gravity of the body, is equal to the sum of the products of the weight of each mass into the distance of its center of gravity from that plane, and this divided by the total weight of the body. Furthermore, the masses whose moments are thus obtained may form one body or any number of bodies. In the latter case, the center of gravity obtained would be the center of gravity of all the bodies. The *exact point* of the center of gravity is determined from *three* coordinate planes.

If the center of gravity of a solid is supported on a point, the whole body will be in unstable equilibrium.

Center of Oscillation = Center of Percussion, about Axis O .—The center of oscillation P of a mass swinging or oscillating about a fixed axis passing through O , is a point at which if the whole mass were concentrated the oscillation would remain the same. The center of percussion P of the mass suspended from the axis at O , is that point at which if a horizontal force be applied there will be no shock at O . The two points P are identical. Let any mass M , Fig. 48, be suspended from an axis at O . Let G be the cen of grav of the mass, C the center of gyration, and P the center of oscillation or percussion; and let y_0 , r and l be the respective distances to these points from the plane X ; r being the radius of gyration of the mass about O , and l the radius of oscillation. Then will r be a mean proportional between y_0 and l , so that

Fig. 48.

$$\text{radius of oscillation } l = \frac{r^2}{y_0} = \frac{(\text{radius of gyration})^2}{\text{dist to cen of grav}} \dots \dots \dots (47)$$

To illustrate: For a rod of length L and of uniform section, suspended freely from its upper end: $y_0 = \frac{L}{2}$, $r^2 = \frac{L^2}{3}$, and $l = \frac{2}{3}L$.

Note that O and P are interchangeable; that is, if P becomes the axis, then O will be the center of oscillation or percussion.

The theory of the compound pendulum is based on the above principles.

Impact or Collision.—The "line of impact" of two bodies in collision is a line normal to the surfaces at the "point of contact," irrespective of the relative motion of the two bodies. Impact is—

Central, when the line of impact coincides with the line joining the centers of gravity of the two bodies; *eccentric*, when it does not.

Direct, when the line of impact coincides with the line of relative motion of the two bodies; *oblique*, when it does not.

Central impact may be either direct or oblique.

Direct impact may be either central or eccentric.

In all cases of impact, action = reaction.

Notation.

m_1 , m_2 , — the respective masses,

c_1 , c_2 , — the respective velocities before impact,

v' , v'' , — the respective velocities at any given instant during impact,

v_1 , v_2 , — the respective velocities after impact,

v , — common velocity at time of greatest compression,

e , — coefficient of restitution in imperfectly elastic contact.

CENTRAL IMPACT FORMULAS.

$$\text{Velocity at time of greatest compression, } v = \frac{m_1 c_1 + m_2 c_2}{m_1 + m_2} \dots\dots\dots (48)$$

$$\text{Coefficient of restitution, } e = \frac{\text{veloc regained after compression}}{\text{velocity lost during compression}} = \frac{v - v_1}{c_1 - v} = \frac{v_2 - v}{v - c_2} \dots\dots\dots (49)$$

For perfectly elastic bodies, e would = 1; but as all bodies are imperfectly elastic, e is always less than unity, showing that there is a loss of energy during impact.

$$\text{Loss of energy due to inelastic impact} = \frac{m_1 m_2}{2 (m_1 + m_2)} (c_1 - c_2)^2 \dots\dots\dots (50)$$

$$\text{Loss of energy due to imperfectly elastic impact} = (1 - e^2) \frac{m_1 m_2}{2 (m_1 + m_2)} (c_1 - c_2)^2 \dots\dots\dots (51)$$

16.—THEORY OF STRESSES IN STRUCTURES.

OUTER AND INNER FORCES.

A structure is designed to resist safely the loads which may come upon it. These loads (which include the weight of the structure itself) together with their attendant reactions, are called the external or *outer forces*; while the stresses which these outer forces produce in the members of the structure themselves, are called the internal or *inner forces*; thus—

Outer forces = { (a.) Loads (=live, dead, wind, snow, etc.).
(b.) Reactions.
Inner forces = (c.) Stresses in the members.

Assuming that the loads acting on the structure are known, the first step is to find one or more of the *reactions*; and from these outer forces the stresses in the members may be determined by the use of the analytical or the graphical methods, or by the two methods combined. In the operation of finding the reactions and stresses it is well to remember the following principles:

PRINCIPLES OF STATIC EQUILIBRIUM.

First.—The algebraic sum of the moments* of the outer forces about any point is equal to zero; from which, considering right-hand (clockwise) moments *plus* and left-hand (un-clockwise) moments *minus*, or vice versa, we have—

Summation of moments = 0: $\Sigma M = 0$ (1)

Second.—The algebraic sum of the components, in any given direction, of the outer forces is equal to zero; from which, considering those downward or to the right, *plus*, and those upward or to the left, *minus*, or vice versa, we have—

Summation of vertical components = 0: $\Sigma V = 0$ (2)

Summation of horizontal components = 0: $\Sigma H = 0$ (3)

Third.—For clearness and simplicity of calculation, in the application of equations (1), (2) and (3), the stresses in certain members of the truss or frame-work may temporarily be considered as outer forces, by cutting the structure in two by certain planes (straight or curved) properly intersecting the members in question—considering that portion of the structure on one side of the cutting plane (usually the left side) as a complete structure; and the stresses in the members so cut, as outer forces acting on the section to produce equilibrium. That is, these *imaginary* outer forces are the stresses to be calculated. (See Figs. 1 and 2.) Generally, only three† *active* members may be cut; thus—

Cut three active members; intersection of either two is }
origin of moments for calculating the stress in the third } (4)
member.

Fig. 1.

* The moment of a force about a given point, as origin, is the product of the force and the shortest distance from the origin to the line of the force.
† See "Notes," page 726, for cutting of four active members.

PRINCIPAL METHODS OF CALCULATION.

Method of Moments.—This method of calculation, using equation (1), is usually employed in determining the reactions at the points of support, the stresses in the chord members of bridges and roofs and in the web members where the chord members are not parallel; the wind stresses in the main vertical members of towers, buildings and similar structures; the compressive stresses in masonry dams; etc.

Method of Shears.—This method, using equations (2) and (3), is usually employed in calculating the stresses in the web members of any frame-work connecting parallel chords, as the lateral systems of bridges; the web members of simple bridge and roof trusses; the bracing of towers; the shears in dams; etc.

The stress in any vertical web member which "takes up" all the shear is equal to the algebraic sum of the vertical components of the outer forces to the left of the section cutting the member; and the stress in any diagonal member is equal to the vertical shear multiplied by the secant of angle of inclination of that member with the vertical.

The term "vertical" may be used in any uniformly specific direction usually at right angle with the axis of the structure and parallel with the direction of the prevailing outer forces. To epitomize:

Stress in any member carrying all the shear = vertical shear $\times$ secant of angle of inclination with the vertical. }

The above five laws are fundamental in the determination of the stresses in any structure which is statically determinate.

Graphical Methods.—The most common methods of determining stresses is by graphics, which may be performed by "moment diagram" or by diagrams involving the principle of the "triangle of forces" (see Mechanics, Figs. 31 to 35). The latter is called Maxwell's method and is the most used. (See Figs. 4, etc., following.)

PRACTICAL APPLICATION OF PRECEDING PRINCIPLES.

CASE A. LOADS AND REACTIONS VERTICAL.

Problem.—Find the dead-load stresses in a 6-panel Pratt truss 120-ft. span, 23 ft. in height center to center of chords; assuming a dead load per truss at 500 lbs. per lin. ft. and acting at the lower panel points, Fig. 2.

Fig. 2.

Calculation.—Stresses are usually in thousand-pound units and calculated to the nearest hundred pounds; thus, 64.7 = 64700 lbs.; 64.0 = 64000 lbs.; 64 = 64000 lbs., etc. That is, where the stress is abbreviated to the thousand-pound unit there should be one figure to the right of the decimal point, whether it is a significant figure or merely zero, to show that the stress is in abbreviated form. The sign (—) before, or (c) after, the stress indicates that the member is in compression, as — 64.7 = 64.7c; while the signs (+) and (t) indicate tension, as + 64.7 = 64.7t.

$$\text{Load per panel per truss} = 500 \times 20 = 10000 \text{ lbs.} = 10.0.$$

Reaction at Left Support.—Assuming the panel lengths as unity and taking moments about the right hand abutment B , using equation (1), $\Sigma M=0$, we have,

$$R_1 \times 6 - 10.0 (5 + 4 + 3 + 2 + 1) = 0.$$

Hence, reaction $R_1 = \frac{150.0}{6} = 25.0$, acting upward.

Lengths of Members.—All horizontal or chord members are 20-ft.; all verticals (posts and end suspenders) are 23-ft.; hence, all diagonals (bars and end posts) are

$$\sqrt{20^2 + 23^2} = 30.48\text{-ft.} \quad \text{Thus, hor} = 20; \text{ver} = 23; \text{diag} = 30.48.$$

Trigonometric Ratios.—The angle α , Fig. 2, is the angle of inclination of the diagonal members with the vertical; and its two functions, $\tan \alpha$ and $\sec \alpha$, are respectively employed in calculating the stresses in the chords and diagonal members of bridges with parallel chords.

BENDING MOMENTS AND CHORD STRESSES:

Let O , Fig. 3, be the origin of moments at any panel point of either chord, obtained by cutting three active members, see equation (4), and let it be required to find the stress in the opposite chord member so cut. Let any number of panel loads P_1 act to the left of O , and any number of panel loads P_2 act to the right of O , on the span Nl ; in which

l = length in feet of one panel,

N = number of panels in the span,

n_1 , a = number of panels from R_1 to P_1 and O , respectively,

n_2 , b = number of panels from R_2 to P_2 and O , respectively.

Fig. 2

Then, Bending moment at $O = M_0 = \frac{\Sigma P_1 n_1 \cdot bl + \Sigma P_2 n_2 \cdot al}{N}$ (6)

And if d represents the effective depth of truss, we have,

Stress in chord member = $\frac{M_0}{d} = \frac{M_0 \tan \alpha}{l} = \frac{\Sigma P_1 n_1 b + \Sigma P_2 n_2 a}{N} \tan \alpha$ (7)

which are the general equations for finding the bending moments and chord stresses without first finding the reactions.

Equations (6) and (7) are, however, very little used, and it is probably best for the beginner to employ equations (8) and (9), following, in which the reaction R_1 must first be determined.

Then, Bending moment at $O = M_0 = R_1 \cdot al - \Sigma P_1 \cdot x_1 l$ (8)

And, Stress in chord member = $\frac{M_0}{d} = (R_1 a - \Sigma P_1 x_1) \tan \alpha$ (9)

in which x_1 = number of panels from P_1 to O .

SHEARS AND WEB STRESSES:

Let O , Fig. 3, be the line of shear cutting usually two or three active members, including one web member which takes up all the shear. Then—

Vertical shear at $O = S_0 = R_1 - \Sigma P_1$ (10)

Stress in web member = $(R_1 - \Sigma P_1) \sec \alpha$ (11)

in which α = angle of inclination of web member with the vertical,

and ΣP_1 = sum of all loads to left of cutting line.

Stresses in Chord Members by Method of Moments: $\Sigma M=0$.—In addition to determining the amount of stress in the various members of a structure, it is of course necessary that the kind of stress, whether tensile or compressive, be known in each case. Certain rules may be followed in determining the amount and kind of stresses in statically determined structures, as included in the following steps:

First.—Draw a plane through the structure cutting three active members, including the one to be calculated. The point of intersection of any two of the members will be the center of moments for determining the stress in the third.

Second.—For the member in question, find the intersection of the other two members or "center of moments" about which the moments of the outer forces, acting on the section to the left of the cutting plane, are to be taken. These will include the reaction at the left abutment; and the moment equation, $\Sigma M=0$, will include also the required stress assumed temporarily as an outer force and acting at the right of the cutting plane.

Third.—Take moments about the center of moments, assuming that the above last mentioned unknown force (the required stress) is *plus* (+) and acts away from the section. All other forces tending to produce moments in the same direction as the above may be considered as (+) forces and their moments as (+) moments; while all other outer forces, that is, forces tending to produce moments in the *opposite* direction may be considered as (−) forces and their moments as (−) moments.

Fourth.—If, in the equation $\Sigma M=0$, the result of the required stress is a (+) quantity, the member is in tension; while if it is a (−) quantity the member is in compression. Thus,

Assume required stress as +S acting away from the section (12)

If the result of S is +, the member is in tension (13)

If S is −, the member is in compression (14)

Table 1 is based on the above methods and rules, which will be found useful to the young engineer. The experienced engineer can usually tell the *kind* of stress by inspection, but there are many cases in complex structures where the rules have to be followed.

1.—SHOWING CALCULATION OF CHORD STRESSES, FIG. 2.

Member.	Cutting Plane	Method	Center of Moments.	Equation.	Calculation.	Stress.	Remarks.
2	C-C	$\Sigma M=0$	U_1	$S_2 = R_1 \tan \alpha$	$25.0 \times .87 = +21.7$	21.7t	$\{ R_1 = 25.0;$ $\tan \alpha = .87$
1	U_1-L_1	$\Sigma M=0$	U_1	$S_1 = R_1 \tan \alpha$		21.7t	$\{ \text{Also, from}$ $\Sigma H=0,$ $S_1 = S_2$
3	d-d	$\Sigma M=0$	U_2	$S_3 = (R_1 \times 2 - P_3 \times 1) \tan \alpha$	$40.0 \times .87 = +34.8$	34.8t	
4	d-d	$\Sigma M=0$	L_3	$S_4 = -(3R - 3P) \tan \alpha$	$-45.0 \times .87 = -39.1$	39.1c	$\{ 3P = P_3 \times$ $\{ 2 + P_1 \times 1.$ $2R = R_1 \times 2$
5	C-C	$\Sigma M=0$	L_2	$S_5 = -(2R - P) \tan \alpha$	$-40.0 \times .87 = -34.8$	34.8c	

Stresses in Web Members by Method of Shears: $\Sigma V=0$.—The shear method is usually adopted where a single web member in a panel takes up all the shear, as in Fig. 2, in which top and bottom chords are parallel and at right angle with the prevailing outer forces. In such cases the following steps may be employed:

First.—Draw a plane, cutting the web member in question and also the upper and lower chords. It is clearly evident that the stresses in the chords can have no vertical component to assist in "taking up" the shear, since they are at right angle with the shear, hence it must be taken up by the web or shear member.

Second.—Find the algebraic sum of the vertical outer forces to the *left* of the cutting plane, and this will be equal in magnitude and *opposite* in direction to the *vertical* component of the required stress in the member, acting at the right of the cutting plane to produce equilibrium. If the required stress acts away from the cutting plane the member is in tension (+), while if it acts toward the cutting plane the member is in compression (−).

Table 2 is based on the above rules, although the algebraic signs giving direction can usually be dispensed with.

FINDING CALCULATION OF WEB STRESSES—Fig. 2.

Equation.	Calculation.	Stress.	Remarks.
$S_6 = -R_1 \sec \alpha$	$\left\{ \begin{array}{l} -25.0 \times 1.325 = \\ -33.1 \end{array} \right\}$	33.1c	$\left\{ \begin{array}{l} R_1 = 25.0; \\ \sec \alpha = 1.325. \end{array} \right.$
$S_1 = S_2 = 0$	$21.7 - 0 = 21.7$	21.7t	See Table 1.
$S_7 = P_5 = 0$	$10.0 - 0 = 10.0$	10.0t	$\left\{ \begin{array}{l} \text{Cutting} \\ \text{plane,} \\ \text{curved.} \end{array} \right.$
$S_8 = (R_1 - P_5) \sec \alpha$	$15.0 \times 1.325 = 19.9$	19.9t	
$S_9 = -(R - 2P)$	$-25.0 + 20.0 = -5.0$	5.0c	
$S_{10} = (R - 2P) \sec \alpha$	$5.0 \times 1.325 = 6.6$	6.6t	
$S_{11} = 0$		0.0	$\left\{ \begin{array}{l} \text{Cutting} \\ \text{plane,} \\ \text{curved.} \end{array} \right.$

the span and loads being symmetrical it is necessary to go to the center of the span only, the other half span being neglected.

Summary.—In addition to the outer forces being in equilibrium conditions (1), (2) and (3), it is also true that all forces, inner or outer, at any panel point or joint of the truss are in equilibrium. The equations. Fig. 4 (using above calculations of 120-lb) will explain:

Fig. 4.

Forces acting toward the joints denote compression; from the joints denote tension.

—In the above figure the inner forces or stresses in the truss are represented as outer forces acting at the several panel points, so that the forces at each joint will form a closed polygon in equilibrium (see Mechanics, Figs. 34, 35). Thus, the space U is a triangle; at L_1 , a rectangle; at U_1 , a trapezium; etc., and so on.

—To distinguish the stress in the stress diagram corresponding to the number in the skeleton diagram of the truss, is called Bow's notation. For example, the line BC in the stress diagram, Fig. 6, represents the diagonal member lying between the triangular spaces U and L in the skeleton diagram, Fig. 4. The space U covers the whole truss from L_0 to L'_0 , while the space L is made to cover the whole truss between the same points; so that AU corresponds to U_2 ; AL to L_0L_1 ; BL to L_1L_2 ; etc. Some engineers prefer to place the letters around the outside of the truss between the lines of the truss, instead of L being used universally for the whole space, to use L_a , L_b , L_c , etc., between L_0L_1 , L_1L_2 , etc.

L_2L_3 , etc., or to use entirely different letters, as F, G, H , etc.; while some prefer the use of the letters X and Y to represent, respectively, the upper and lower outside spaces of the truss. There is, however, no real principle involved in these various customs.

Fig. 5. Force polygons at joints (Fig. 4).

Graphical Method.—The principle of force polygons at the joints of a structure has led to the rapid solution of stresses by the graphical method. It will be noticed that Figs. 5, if "fitted together," will form the complete graphical stress diagram of half the truss—Fig. 6, showing the complete stress diagram of the whole truss, the two halves being symmetrical.

Fig. 6.

Hence if the loads and reactions are laid off to proper scale, forming a closed polygon of outer forces called the *load line*, the lines drawn parallel with the members of the skeleton diagram of the truss and properly intersecting one another, will represent by scale the actual stresses in the members. The following rules will be found universal in application for loads and reactions in any direction or applied at any points of the structure.

GENERAL RULES FOR STRESS DIAGRAM.

Order of Considering Forces Around Joints.—

- 1°. Draw skeleton of truss accurately to a good scale.
- 2°. Show T loads at top joints and B loads at bottom joints of truss.

Note.—In ordinary cases where T and B loads at the *abutments* are vertically downward and opposite in direction to the reactions at those points, these loads may be omitted—so far as the stresses in the trusses are concerned—and the reactions diminished accordingly; but the total reactions must be considered in designing the supports themselves. Where the loads and reactions are not in the same straight line, both must be included.

- 3°. Find the reactions— R_1 = left-hand; R_2 = right-hand.
- 4°. Load-line = reactions and loads forming closed polygon of outer forces.

Note.—Begin with one of the reactions and draw, in the directions of the forces, the closed polygon of outer forces—reactions and loads—considering them in right-handed (clockwise) or left-handed (counterclockwise) order around the truss, as per the following:

5°. *Outer forces around truss considered in clockwise order:*

Beginning with R_1 —(mainly for T loads, at top of truss)—

- { Draw stress diagram to left of load line;
 { Consider forces around joints in clockwise order } . (15)

Beginning with R_2 —(mainly for B loads, at bottom of truss)—

- { Draw stress diagram to left of load line;
 { Consider forces around joints in clockwise order } . (16)

For (15)

For (17)

For (19)

6°. *Outer forces around truss considered in un-clockwise order:*

Beginning with R_1 —(mainly for B loads, at bottom of truss)—

- { Draw stress diagram to right of load line;
 { Consider forces around joints in un-clockwise order } . (17)

Beginning with R_2 —(mainly for T loads, at top of truss)—

- { Draw stress diagram to right of load line;
 { Consider forces around joints in un-clockwise order } . (18)

For (16)

For (18)

For (20)

For trusses loaded with T loads, at top, and B loads, at bottom chords, (15) and (16) may be combined in (19); while (17) and (18) may be combined in (20); as follows:

7°. *Outer forces around truss considered in clockwise order:*

- { Beginning with R_1 or R_2 —(for both T and B loads)—
 { Draw stress diagram to left of load line;
 { Consider forces around joints in clockwise order } . (19)

8°. *Outer forces around truss considered in un-clockwise order:*

- { Beginning with R_1 or R_2 —(for both B and T loads)—
 { Draw stress diagram to right of load line;
 { Consider forces around joints in un-clockwise order } . (20)

Remarks.—The load-line diagrams above, illustrating (15) to (20) inclusive, simply show the *order* of considering the forces at the joints, but not their direction. Note that if the outer forces are all vertical, the load line will be a vertical line.

Order of Considering Joints.—So far, we have considered the order of drawing the outer forces to form the load-line polygon; and the order of considering the forces around the joints for a stress diagram either to *right* or *left* of the load line. We will now consider the order of proceeding from one joint to another of the truss in drawing the stress diagram; bearing in mind that it is sometimes essential to begin at the end of the truss which

has the larger reaction, as a stress diagram is simply a system of triangulation and the larger the initial base the better. There are other reasons, however, which must be considered; namely, the nature of the loading and the general convenience of always starting from the one end. In trusses which support moving loads the loads are made to come on from the right, and the left reaction is taken as the initial base of the stress diagram. In other words, we usually start with joint L_0 of the truss.

In following from joint to joint we must select the one which has, for the given loading, *only two unknown stresses* whose directions are known, because—with one force given, in magnitude and direction—

Two unknown forces only, whose directions are known, can be solved by a "triangle of forces;" and this fact determines the order } (21)
of considering joints.

PRACTICAL APPLICATION OF PRECEDING GRAPHICAL RULES.

Graphical Solution of Case A; Loads at Bottom Joints.—Data: 6 panels at 20-ft. = 120-ft. span; height of truss = 23 ft.; load per joint = 10,000 lbs.; reactions, each = 25,000 lbs.

Draw the truss very carefully to scale, large enough so lines in the stress diagram can be drawn parallel with the members of the truss, with sufficient accuracy.

In accordance with (17), beginning at the left-hand end of the truss, lay off consecutively in direction and intensity, by scale, the outer forces $R_1 = 25.0$ (upward); $P_5, P_4, P_3, P_2, P_1 = 10.0 + 10.0 + 10.0 + 10.0 + 10.0$ (downward); and $R_2 = 25.0$ (upward).

Draw the stress diagram as per Fig. 6, considering the order of the forces in un-clockwise order around each joint and noting that when a stress is drawn in direction away from the joint, the member is in tension; while if drawn in direction toward the joint, the member is in compression. The arrows in Figs. 5 show the direction of the stresses of each polygon of forces, indicating the nature of the stress in each case.

Table 3 shows the order of considering the joints, the given and required forces at each joint, and the nature of the stresses in the members.

3.—GRAPHICAL METHOD OF SOLVING CASE A, FIGS. 4, 5 AND 6.

Order of Considering Joints.	Name of Joint.	Forces (Fig. 4).		New Intersection (Fig. 6).	Direction of forces in force polygon.		Remarks.
		Given.	To find.		From the joint, denoting tension (+).	Toward the joint, denoting compression (-)	
1	L_0	R_1	LA, UA	A	$LA = +21.7$	$UA = -33.1$	
2	L_1	AL, L, L_1	LB, AB	B	$LB = +21.7$ $AB = +10.0$		
3	U_1	UA, AB	UC, BC	C	$BC = +19.9$	$UC = -34.8$	
4	L_2	CB, BL, L, L_1	LD, CD	D	$LD = +34.8$	$CD = -5.0$	
5	U_2	UC, CD	UE, DE	E	$DE = +6.6$	$UE = -39.1$	
6	U_3	UE	EE', UE'	E'	$EE' = \pm 0.0$	$UE' = -39.1$	{Point E = E'.
7	L_3	EE', DE, DL, L, L'	$LD', E'D'$	D'	$D'E = +6.6$	$LD' = +34.8$	

loads at Top Joints.—The following is a graphical solution of the loads at the joints acting at the top instead of at the bottom of the truss. Two methods are shown, namely, (15) and (18). The stress diagram is a supplement of the other, that is, revolved

Fig. 7.

Fig. 9.

reactions, clockwise. (18). Loads and reactions, unclockwise. Forces around joints, clockwise. Compare the above with the diagrams obtained for bottom joints, 5 and 6, and note that the difference in the stresses is vertical members.

loads at Top and Bottom Joints.—Before leaving the analysis let us consider another case—top cord joints loaded with

Fig. 10.

In this case either (19) or (20) may be used. We will use (19)—the stress diagram to left of load line (R_1 , T , R_2 , B).

reactions clockwise. Forces around joints clockwise.

The stress diagram to left of load line is complete in full lines. The right-hand half of the stress diagram is in dotted lines. The stress diagram is symmetrical and hence one half of the stress diagram is all that is needed in practice.

Fig. 11.

all the T loads, is known in intensity, direction and position, passing through T_2 normal to the roof; R_1 is known in direction and position, passing vertically through L . Let O be the point of intersection of P and R_1 , and considering it the center of moments of all the outer forces, we have, from $\Sigma M = 0$, that R_2 must be in the direction RO , passing through the center of moments O .

The stress diagram, Fig. 15, is drawn by rule (18), page 311:

Fig. 14— (18).—Loads and reactions, un-clockwise.

Forces around joints, un-clockwise.

Note.—As the left end is the roller end the reaction R_1 must be vertical.

Fig. 16 is the stress diagram for the same truss, treated as per Case Cb by similar analysis.

(15). Loads and reactions, clockwise.

Forces around joints, clockwise.

Note.—As the right-hand end is the roller end the reaction R_2 must be vertical.

Remarks.—The two conditions (a) and (b) of Case C are applied in practice to the roof truss for maximum wind stress in each of the members. In addition to these the members of course are designed for snow-, dead-, and live-loads, if any. For these latter cases, however, the reactions are vertical and the graphical methods are simple. (See Roofs, Section 46).

Case D. Three-hinged Arch; Vertical Loads.—Three-hinged arch (Fig. 17) with a load P acting on the left-hand girder, one panel from the center of the span. The span is hinged in the center and at each abutment, and as there can be no moments at these hinges the lines of reactions must pass through them, as follows:

- For a load at center of span, R_1 takes the direction LO , and R_2 takes the direction RO .
- For a load at the left of the center as P , R_2 takes the direction RO , intersecting the line of the force P at H ; whence R_1 takes the direction LH .
- Similarly, for a load P' at the right of the center, R_1 takes the direction LO , intersecting the line of the force P' at H' ; whence R_2 takes the direction RH' .

Fig. 18 is a stress diagram of the arch, for the load P , Case Db, above. For this load the dotted members, Fig. 17, have no stress.

(18). Loads and reactions, un-clockwise.

Forces around joints, un-clockwise.

Note.— R_2 and P determine R_1 .

Remarks.—The + and - signs for the members indicate respectively whether they are in tension or compression.

(FOR WEIGHTS AND SPECIFIC GRAVITIES, SEE SECTION 27.)

A.—CHEMICAL.

Composition of Matter.—If a drop of water could be magnified to the size of the earth it is estimated that the countless *atoms* of which the drop is composed would each appear to be about the size of a bird's egg. It would also be seen that all the atoms would be in groups of three, each group or *molecule* being composed of two atoms of hydrogen and one of oxygen. Subject the drop of water to a galvanic current and it will cease to exist as water, being decomposed into its two *elements*—hydrogen and oxygen. In other words, the molecules forming the *compound*, water, will become disintegrated, all the atoms of hydrogen passing off as hydrogen gas, and all the atoms of oxygen passing off as oxygen gas. Conversely, if now the two evolved gases are mixed and sufficiently heated they will unite with explosive force into the same molecular composition as before, re-forming the drop of water. In the above processes, the decomposition and recombination of the substance water, none of the atoms have been divided or destroyed.

Old Atomic Theory.—Up to about the year 1898 the last sentence of the preceding paragraph might have been concluded about as follows, as was generally accepted: "Because the atom is indivisible and indestructible, representing the smallest particle of an element of *matter*; hence when we say that matter is indestructible we mean simply that the atoms of which all matter is composed are indestructible."

Recent Discoveries.—The recent discoveries of the Hertzian ray and its practical use in wireless telegraphy; of the Röntgen or X-ray, by means of the Crooke's or vacuum tube, 1895; of the Becquerel ray, exhibiting the radio-activity properties of the element uranium, in 1896; and later, the discovery of the radio-activity properties of the elements thorium, polonium, radium and actinium, have resulted in shaking the old atomic theory of Dalton, which had lasted for a century.

The Corpuscular Theory.—It is now believed that each atom, previously supposed to represent the smallest particle of matter, is really composed of a great number of smaller particles called *corpuscles*. For instance, the smallest and lightest atom known, that of hydrogen, contains about 1,000 such corpuscles; while one of the heaviest atoms, that of radium, contains about 200,000. It is further submitted that these corpuscles are so infinitely small that the unoccupied space in the atom is almost infinitely greater than the corpuscles themselves in comparison, and that they are vibrating or traveling through this space with velocities of many thousands of feet per second. This becomes all the more amazing when it is stated that the diameter of a molecule, which is composed of many atoms, is in the neighborhood of $\frac{1}{250,000,000}$ of an inch.

The corpuscular theory has been advanced in order to explain some of the recent discoveries cited above. Radium, for instance, is constantly giving off heat to surrounding objects without any visible source of supply. The heat is evidently furnished by the breaking up or disintegration of the atoms; i. e., by the transformation of part of the corpuscular energy of the atoms, into heat. The balance of the energy is dissipated in the form of various kinds of rays. On this theory the laws of the conservation of energy still hold, for it has been observed that all of the radio-active substances gradually lose in weight. It is estimated that radium will disperse about $\frac{1}{2}$ its mass in 1500 years, and $\frac{1}{8}$ of it in 10000 years. Thorium and uranium act much more slowly, requiring in the first instance about 1000 million years, and in the second instance 10000 million years. Moreover, all substances are supposed to be radio-active to some extent, i. e., their atoms are gradually breaking up into corpuscles and the corpuscular energy is being transformed into other kinds of energy. In line with this argument, with the scent of flowers and of many substances.

Looking at the subject, then, from this point of view we may consider *matter* as the great storehouse of *energy*; and some idea of the efficiency

we had from the following: The hydrogen-oxygen flame is known, yet the amount of heat energy given off spontaneous combustion of an equal weight of hydrogen. In the case of the *atoms* burst, releasing the stored-up corpuscular energies only. The corpuscular energy is vastly the greater than the total work of disintegration of a small amount of radium produces heat equivalent to the generation of one horse-power! How to utilize, economically, the tremendous amount of energy in matter is a problem. We have seen that the ordinary combustion releases but an infinitesimal part of this stored energy, and that only a small percentage of even this is made available. Scientists are even now further speculating on the possibility of the corpuscles themselves being divisible into more minute particles, and of greater sources of energy, some of them advancing the theory that the corpuscles are made up of the invisible and universal ether. Others speculate on the possibility of corpuscles being

Theory.—Long before the recent discoveries, which led to the development of part of the atomic theory of Dalton, chemists predicted that at some future time it would be found possible to transmute one element into another, there was little doubt that any one element could be transmuted into any other element of a different kind. It was Soddy who is credited with the discovery of the transmutation of elements into an entirely different element, helium; his discovery has brought forth new theories regarding the nature of matter:

"The conception of the ultimate unit is the electron, and this, in an electrical conception, is in reality a material conception of the atom of matter. The electron could be defined as a unit of matter capable of isolation and of free movement; it is a definite amount or 'charge' of negative electricity; it is the smallest possible amount known to exist; for electricity, no doubt, has been shown to consist of discrete particles or units, and not of a continuous space continuously. Unlike the atoms of matter, only one electron is known, consisting of the same amount or charge of electricity with identical properties in all its various manifestations. Each atom of matter contains in the normal condition a certain number of electrons, which it is capable of losing, and conversely that it may gain electrons, so that an atom which normally possesses without deep change. An atom with one or more electrons less than its normal state is positively charged and is often called a *positive ion*. An atom with one or more electrons in excess is a *negative ion*."

—*Scientific American*.

—At present there are about 90 known elements, that is, 90 different kinds of atoms are all alike in the particular element but different from any other element. Table 1 gives a fairly complete list of the elements, their symbols and some of their properties. The 2nd column gives the general way only, the division of the elements into three groups, A, B, C. In the third column the names of those elements which are common and widely distributed are in SMALL CAPITALS; the names of those which are rare are printed in *italics*. The atomic weights are given for the elements, both of which are frequently used: The atomic weight of an atom of hydrogen = 1 ($\therefore O = 15.87$). The atomic weight of an atom of oxygen = 16 ($\therefore H = 1.008$). The atomic weight of an atom of carbon = 12 ($\therefore C = 12$). (a), is the most used. The 7th column shows which are metals; they are marked Met.; the other 13 are metalloids. The 8th column gives the order in which many of the elements exist in nature, earth, air and sea combined; and opposite the name is given the percentage by quantity of the total mass. Thus, oxygen is given as comprising one-half, silicon one-quarter, aluminum one-eighth of the total. The 10th column shows the state of the element at ordinary temperatures, as solid, liquid and gaseous. The third from the last gives the molecular volumes of some of the elements; that the elements are single, double, triple, etc., in the molecule. The last column is self-explanatory.

* Solid (S), liquid (L) or gaseous (G) state. ‡ Sulphur is sometimes hexatomic. a. antedates.

† 1, monatomic; 2, diatomic; 3, triatomic; 4, tetraatomic; 5, pentatomic; 6, hexatomic.

Compounds.—A compound is a chemical union of two or more elements, each molecule of the compound being a perfect likeness in miniature of the compound itself. It differs from a *mixture* in that no chemical change takes place in the latter, the original molecules of each of the substances mixed remaining intact.

Compound substances are generally named so as

- To denote the constituent elements.
- To denote the kind of molecular grouping of the elements.
- To denote the nature of a resulting compound by the addition or subtraction of some particular kind of element.

Simple Combinations.—**Idea.**—Many of the non-metallic elements when combined with a simple basic one take on the suffix *ide* or *et*, as, for instance,

Iron	and oxygen form	iron oxide (oxide of iron).
Lead	chlorine	lead chloride (chloride of lead).
Potassium	bromine	potassium bromide (etc.).
Hydrogen	sulphur	hydrogen sulphide (sulphuret of hydrogen).
Copper	sulphur	copper sulphide (etc.).

But by reason of the fact that two substances often unite in different proportions the names of the resulting compounds are so contrived by Latin prefixes and suffixes as to indicate quite directly its molecular composition. Thus,

Suboxide of copper	Cu_2O	Ratio of O is <	1 : 1
Protoxide of manganese (= monoxide)	MnO	" "	1 : 1
Deutoxide of lead	PbO_2	" "	> 1 : 1
Sesquioxide of manganese	Mn_2O_3	" "	3 : 2
Binoxide of silica (= dioxide)	SiO_2	" "	2 : 1
Teroxide of chromium (= trioxide)	CrO_3	" "	3 : 1
Peroxide of Nickel	Ni_2O_4	" "	max.

The same prefixes may be applied to other compounds, as chlorine, sulphur, etc.

Acids, Bases and Salts.—When an *acid* and a *base* or *alkali* are brought together chemically in the proper proportions, they neutralize each other, and the resulting chemical products are, 1st, *water* and 2nd, *salt*.

An *acid* may be defined as a substance containing hydrogen, which it readily exchanges for a metal when treated with a metal or metal compound called a *base*.

A *base* is a substance containing a metal combined with hydrogen and oxygen, which metal it readily exchanges for hydrogen when treated with an acid.

A *salt* is a neutral substance, one of the products of the action of an acid on a base, the other product being *water*.

Oxides and Hydroxides.—An *oxide* is a compound of oxygen, more especially with a *metal* or *metalloid*. The principal classes of oxides are (1) basic or metallic oxides, and (2) acid oxides or acid anhydrides. Examples: (1), calcium oxide (CaO); (2), sulphuric anhydride (SO_3). A *hydroxide* may be formed (1) by treating oxides with water, and (2) by decomposing salts by the addition of soluble hydroxides to their solutions. Examples: (1), $CaO + H_2O = Ca(OH)_2$; (2), $MgSO_4 + 2NaOH = Na_2SO_4 + Mg(OH)_2$.

Acid Combinations.—An acid is a compound containing, in each molecule, one or more atoms of hydrogen which may be displaced by a metal or by a compound possessing metallic functions. If the acid molecule contains one hydrogen atom it is *monobasic*; two hydrogen atoms, *bibasic*; three hydrogen atoms, *tribasic*; more than one hydrogen atom, *polybasic*, etc.

When acid contains oxygen the suffix *-ic* is usually given to the characteristic element of the compound, as sulphuric acid for H_2SO_4 . But if two acids can be formed with oxygen from the same characteristic element, that one which is the more highly oxidized has the suffix *-ic* while the other, the less oxidized, takes on the suffix *-ous*. In cases where more than two acids are formed by different proportions of oxygen the above are

further modified by the prefixes *hyper*—, meaning over, and *hypo*—, meaning under. Thus we may have according to the relative proportions of oxygen present, say in the sulphur acids:

- | | | | |
|-----|-----------------------------|-------------|--|
| (a) | <i>hyposulphurous</i> acid, | H_2OS_2 | (Least proportion of oxygen.) |
| (b) | <i>sulphurous</i> " | H_2SO_3 | (Less proportion of oxygen.) |
| (c) | <i>hypersulphurous</i> " | " | (<i>Per</i> often used instead of <i>hyper</i> .) |
| (d) | <i>hyposulphuric</i> " | " | (This is preferable to c.) |
| (e) | <i>sulphuric</i> " | H_2SO_4 | (Greater proportion of oxygen.) |
| (f) | <i>hypersulphuric</i> " | $H_2S_2O_8$ | (Greatest proportion of oxygen.) |

Salts.—We have seen that an acid contains one or more atoms of hydrogen which *may be* replaced by metallic atoms or basic radicals. When such a change takes place in an acid the resulting compound is a salt. The names of the salts so formed are related to the acids which produce them, as

—ic acids form —ate salts.

—ous —ite "

hypo—ous " " *hypo*—ite "

Thus, sulphuric acid (H_2SO_4) and soda (Na) form *sulphate* of soda (Na_2SO_4); *hyposulphurous* acid (H_2SO_3) and soda form *hyposulphite* of soda, etc.

In line with the above definition we may say further that any base in which one or more of the hydrogen atoms have been replaced by non-metallic atoms or acid radicals, is a salt.

A salt may be formed by compounding a metallic oxide with an anhydride.

Periodic Law.—"The properties of the elements, as well as the forms and properties of the compounds, are in periodic dependence on, or form periodic functions of, the atomic weights of the elements." This law, conceived by Newlands and later perfected by Mendeléeff, Meyer and others, is a fundamental law of Chemistry. If the elements are arranged in series on an ascending scale, according to their atomic weights, this series can be made to exhibit Family Groups showing common characteristics, in much the same manner as the natural divisions or classifications of the mineral, vegetable and animal kingdoms.

Table 2 is such a grouping, by Meyer. The inclined lines indicate a spiral or continuous series if the table were wrapped around a cylinder. The vertical columns show the Groups, I, II, III, etc., with sub-divisions A and B. Each group has common characteristics, while those of the sub-divisions are still more in common. The vacant spaces are for other elements, most of which have not yet been discovered or their atomic weights determined. It is a significant fact that by means of this law Mendeléeff foretold the existence of some of the elements long before their discovery, and calculated their atomic weights correctly.

Chemical Substances and Their Common Names.—

(Knowledge Year Book.)

Alum—Sulphate of aluminum and potassium.	Realgar—Sulphide of arsenic.
Aqua fortis—Nitric acid.	Red lead—Oxide of lead.
Aqua regia—Nitro-hydrochloric acid.	Rochelle salt—Sodium potassium tartrate.
Calomel—Mercurous chloride.	Sal ammoniac—Ammonium chloride.
Carbolic acid—Phenol.	Salt, common—Sodium chloride.
Caustic potash—Potassium hydrate.	Salt of tartar (potash)—Potassium carbonate.
Caustic soda—Sodium hydrate.	Saltpetre—Potassium nitrate.
Chalk—Calcium carbonate.	Salt of lemon—Oxalic acid.
Copperas—Sulphate of iron.	Slacked lime—Calcium hydrate.
Corrosive sublimate—Mercurous chloride.	Soda, washing—Calcium carbonate.
Cream of tartar—Bitartrate of potassium.	Soda, baking—Sodium bicarbonate.
Epsom salts—Magnesium sulphate.	Soda—Sodium carbonate.
Fire damp—Light carburetted hydrogen, methane.	Spirits of hartshorn—Solution of Ammonia.
Glaubers' salt—Sodium sulphate.	Spirits of salt—Hydrochloric acid.
Grape sugar—Glucose.	Sugar of lead—Lead acetate.
Goulard water—Basic acetate of lead.	Tartar emetic—Potassium antimony tartrate.
Iron pyrites—Sulphide of iron.	Verdigris—Basic acetate of copper.
Jewelers' putty—Oxide of tin.	Vermillion—Sulphide of mercury.
Laughing gas—Nitrous oxide.	Vinegar—Dilute Acetic acid.
Lime—Calcium oxide.	Vitriol, blue—Copper sulphate.
Lunar caustic—Silver nitrate.	green—Ferrous sulphate.
Mosaic gold—Bisulphide of tin.	oil of—Sulphuric acid.
Muriatic acid—Hydrochloric acid.	white—Zinc sulphate.
Plaster of paris—Calcium sulphate.	Volatile alkali—Ammonia.

B.—MINERALOGICAL.

Minerals Compose Rocks.—Mineralogical substances include all those natural objects which belong to the Inorganic Kingdom, whether solid liquid or gaseous. A *mineral* may be defined as a natural, inorganic, homogeneous, chemical substance; while a *rock* is made up of one or more mineral masses mixed in fairly constant proportions throughout.

(a) **Hardness.**—The hardness of a mineral is its resistance to abrasion. There are ten recognized degrees of hardness, typified by the following minerals:

1. *Talc*.—Soft and greasy; easily scratched by finger nail.
2. *Gypsum*.—Not easily scratched by the finger nail.
3. *Calcite*.—Scratches copper coin; is scratched by same.
4. *Fluorite*.—Not scratched by copper; and does not scratch glass.
5. *Apatite*.—Barely scratches glass; easily scratched by a knife.
6. *Orthoclase*.—Easily scratches glass; barely scratched by a file.
7. *Quartz*.—Not scratched by a knife.
8. *Topaz*.—Not scratched by a file.
9. *Sapphire*.—About $\frac{7}{100}$ as hard as diamond.
10. *Diamond*.—Hardest substance known.

(b to l). **Other Physical Characteristics.**—Minerals are often identified by the above characteristics of hardness and also by the kinds and degrees of the following:

- (b) tenacity, (c) cleavage, (d) fracture, (e) feel, (f) taste, (g) odor, (h) lustre, (i) color, (j) transparency, (k) translucency, (l) opacity, etc.

3.—CLASSIFICATION OF IMPORTANT MINERAL SPECIES.*

I. Native Elements.

A Series.—Non-basic or electro-positive elements.

1. Gold Group.—Gold, silver, hydrogen, potassium, sodium, etc.
2. Iron Group.—Platinum, palladium, mercury, copper, iron, zinc, lead, cobalt, nickel, chromium, manganese, calcium, magnesium, etc.
3. Tin Group.—Tin, titanium, zirconium, etc.

B Series.—Elements generally electro-negative.

1. Arsenic Group.—Arsenic, antimony, bismuth, phosphorus, vanadium, etc.
2. Sulphur Group.—Sulphur, tellurium, selenium.
3. Carbon-Silicon Group.—Carbon, silicon, diamond, graphite.

C Series.—Elements always negative.

1. Chlorine, bromine, iodine.
2. Fluorine.
3. Oxygen.

II. Sulphides.—Sulphides, tellurides, selenides, arsenides, antimonides, bismuthides.

A. Binary Compounds.—Sulphides and tellurides of metals of the sulphur and arsenic groups.

- (a) Realgar Group. RS . Realgar, As_2S_4 .
- (b) Orpiment Group. R_2S_3 . Orpiment, As_2S_3
Stibnite, Sb_2S_3
Bismuthinite, Bi_2S_3 .
- (c) Tetradymite, $Bi_2(Te, S)_3$.
- (d) Molybdenite Group. RS_2 . Molybdenite, MoS_2 .

B. Binary compounds.—Sulphides, tellurides, etc., of metals of the gold iron and tin groups.

1. Basic Division.—Dyscrasite, Ag_2Sb ; Ag_6Sb . Domeykite, Cu_3As .
2. Proto Division. RS (or R_2S), RSe , RTe .
 - (a) Galenite Group. Argentite, Ag_2S . Crookesite, $(Cu_2, Tl, Ag)Se$.
Galenite, PbS .
 - (b) Blend Group. Sphalerite, ZnS .
 - (c) Chalcocite Group.
 - (d) Pyrrhotite Group. $\left\{ \begin{array}{l} \text{Cinnabar, } HgS \text{ (or } Hg_2S_3). \text{ Millerite, } NiS. \\ \text{Pyrrhotite, } Fe_7S_8 \text{ mostly.} \\ \text{Greenockite, } CdS \text{ (or } Cd_3S_2). \end{array} \right.$
3. Deuto or Pyrite Division.
 - (a) Pyrite Group. Pyrite, FeS_2 . Chalcopyrite, $CuFeS_2$.
 - (b) Marcasite Group. Marcasite, FeS_2 .
Arsenopyrite, $FeAsS = FeS_2 + FeAs_2$.
Sylvanite.

C. Ternary Compounds.—Sulpharsenites, sulphantimonites, sulphobismuthites.

- (a) Group I. $R(As, Sb)_2S_4 = RS + (As, Sb)_2S_3$.
- (b) Sub Group. $R_3(As, Sb, Bi)_4S_9 = 3RS + 2(As, Sb, Bi)_2S_3$.
- (c) Group II. $R_2(Sb, As)_2S_5 = 2RS + (Sb, As)_2S_3$.
- (d) Group III. $R_3(As, Sb)_2S_6 = 3RS + (As, Sb)_2S_3$.
- (e) Group IV. $R_4(As, Sb, Bi)_2S_7 = 4RS + (As, Sb, Bi)_2S_3$.
- (f) Group V. $R_5(As, Sb)_2S_8 = 5RS + (As, Sb)_2S_3$.

III. Chlorides, Bromides, Iodides.

- A. Anhydrous Chlorides. $R(Cl, Br, I)$; $R_2(Cl, Br, I)$; RCl_3 .
- Halite, $NaCl$. Calomel, $HgCl_2$.
Sylvite, KCl . Sal Ammoniac, NH_4Cl .

B. Hydrus Chlorides.

C. Oxychlorides.

IV. Fluorides.

- A. Anhydrous Fluorides. $\left\{ \begin{array}{l} \text{Fluorite, } CaF_2. \\ \text{Cryolite, } Na_3AlF_6 \text{ (or } 6NaF + AlF_3). \end{array} \right.$
- B. Hydrus Fluorides.

* Mostly in accordance with Dana's Classification.

3.—CLASSIFICATION OF IMPORTANT MINERALS.—Cont'd.

V. Oxygen Compounds.

a. Oxides.

A. Oxides of metals of the gold, iron and tin groups.

1. Anhydrous oxides.

(a) Protoxides. RO or (R_2O) . Cuprite, Cu_2O . Zincite, ZnO .Tenorite, CuO .(b) Sesquioxides, RO_3 . Corundum, AlO_3 . Hematite, FeO_3 .(c) Compounds of protoxides and sesquioxides, $RR'O_4$ (or $RO + R'O_2$).Spinel Group.—Spinel, $MgAlO_4 (= MgO + AlO_3)$.Magnetite, $FeFeO_4$ (or Fe_3O_4) = $FeO + FeO_3$.Franklinite, $(Fe, Zn, Mn)(Fe, Mn)O_4$.Chromite, $FeCrO_4$, or $(Fe, Mg, Cr)(Al, Fe, Cr)O_4$.Uranite, $U_3O_8 (UO_2 + 2UO_3)$.(d) Deutoxides. RO_2 .2. Hydrous oxides. Targite, $H_2F_2O_7$. Diapose, H_2AlO_4 .Gothite, $H_2FeO_4 = H_2FeO_3 + 2FeO_3$.Manganite, $H_2MnO_4 = H_2MnO_3 + 2MnO_3$.Limonite, $H_2Fe_2O_9 = H_2FeO_3 + FeO_3$.

B. Oxides of metals of the arsenic and sulphur groups.

Arsenolite, As_2O_3 .Bismite, Bi_2O_3 .Molybdate, MoO_3 .Tungstate, WO_3 .

C. Oxides of the carbon-silicon group.

Tridymite, SiO_2 .Quartz, SiO_2 .Opal, SiO_2 .

β. Ternary Oxide Compounds.

A. Silicates.

1. Anhydrous silicates.

1° Bisilicates. $RSiO_3$.(a) Amphibole Group.—Wollastonite, $CaSiO_3$.Pyroxene (= Augite), $RSiO_3$; R may be $Ca, Mg, Fe, Mn, Zn, K, Na$.(b) Amphibole Section. Amphibole, $RSiO_3$ (var., Hornblende).2° Unisilicates, R_2SiO_4 .(a) Chrysolite Group.—Chrysolite, $(Mg, Fe)_2SiO_4$. Olivene.(b) Willemite Group.—Willemite, Zn_2SiO_4 .(c) Garnet Group.— $R_3RSi_3O_{12}$.

(d) Vesuvianite Group.

(e) Epidote Group.—Epidote, $H_2Ca_4R_3Si_6O_{26}$.

(f) Mica Group.—Biotite. Muscovite.

(g) Scapolite Group.

(h) Nephelite Group.

(i) Feldspar Group.—Anorthite. Labradorite. Andesite. Oligoclase. Albite. Orthoclase.

3° Subsilicates.

(a) Chondrodite. Tourmaline.

(b) Andalusite. Fibrolite, $AlSiO_5$. Cyanite, $AlSiO_3$.Topaz, $AlSiO_5$.Euclase, $H_2Be_2AlSi_2O_{10}$.(c) Datolite, $H_2Ca_2B_2Si_2O_{10}$. Titamite, $CaTiSiO_5$.

Staurolite.

2. Hydrous Silicates.—I. General Section.

Bisilicates.—Pectotite; lanmontite; okenite; crysocolite; alipite.

Unisilicates.—Calamine; prenite.—Thorite, Pyrosmalite.

Subsilicates.—Allophane.

II. Zeolite Section.

2.—CLASSIFICATION OF IMPORTANT MINERALS.—Cont'd.

Oxygen Compounds—Cont'd.

III. Margarophyllite Section.

Bisilicates.—Talc; pyrophyllite; sepiolite.

Unisilicates.

Serpentine Group.

Kaolinite Group.

Pinite Group.

Hydro-mica Group.

Subsilicates.

Chlorite Group.

B. Tantalates, Columbates.

C. Phosphates, Arsenates, Vanadates, etc.

Anhydrous.

Xenotime, $Y_2 P_2 O_8$.

Apatite Group.—Apatite. Vanadinite.

Antimonates.

Hydrous.

Antimonates.

Nitrates. Nitre, KNO_3 . Soda nitre, $NaNO_3$.D. Borates. Boracite, $Mg_7 B_{10} Cl_2 O_3 = 2Mg_2 B_3 O_{15} + Mg Cl_2$.Borax, $Na_2 B_4 O_7 + 10 aq = 2(Na BO_2 + HBO_2) + 9aq$.E. Tungstates (RWO_4), Molybdates (RMO_4), Chromates ($RCrO_4$).

F. Sulphates.

Anhydrous RSO_4 .Barite Group. Barite, $BaSO_4$. Anglesite, $PbSO_4$.Hydrous. Mirabilite, $Na_2 SO_4 + 10 aq$.Gypsum, $CaSO_4 + 10 aq$ var., selenite.Epsomite, $MgSO_4 + 7 aq$.Copperas Group.—Chalcanthite, $CaSO_4 + 5 aq$.

Alum and Halalrichite Groups.—Copiatite.

Aluminite $AlSO_6 + 9 aq$.Tellurates.—Montanite, $Bi_2 FeO_6 + 2 aq$.

G. Carbonates.

Anhydrous.

Calcite Group. RCO_3 . Calcite, $CaCO_3$.

1. Crystallized: Iceland spar, Fountainblue limestone, Satin spar.

2. Massive: Granular (Saccharoidal): Marble, Statuary marble, Shell marble, Lithographic stone, Breccia marble, Pudding stone marble, Hydraulic limestone.

Soft Compact Limestone: Chalk, Calcareous marl. Concretionary, massive: Oolite.

a. Stalactites.

b. Stalagmites.

c. Calc-sinter. Travertine, Calc-tufa.

d. Agaric mineral.

e. Rock-meal.

Dolomite, $(Ca, Mg)CO_3$.Aukerite, $CaCO_3 + FeCO_3 + x(CaMgC_2O_4)$.Magnesite, $MgCO_3$.Siderite, $FeCO_3$.Rhodochrosite, $MnCO_3$.Smithsonite, $ZnCO_3$.

Aragonite Group.

Hydrous.

3.—CLASSIFICATION OF IMPORTANT MINERALS.—Concl'd.

VI. Hydrocarbons.

1. Simple (no oxygen).

- (a) Marsh Gas Series. $C_n H_{2n+2}$. Includes liquid naphthas and more volatile parts of petroleum; also scheercrite and chrismatite.
Petroleum.—Mineral oil, Kerosene, Bergol, Erdol.
- (b) Olefant or Ethylene Series. $C_n H_{2n}$. Pittolium group of liquids or pettarsphalts (mineral tar) and the paraffines. Paraffin Group.
- (c) Camphene Series. $C_n H_{2n-4}$.
- (d) Benzole Series. $C_n H_{2n-6}$. Benzole liquids.
- (e) Naphthalin Series. $C_n H_{2n-12}$.
Naphthalin (found in Rangoon tar).

2. Oxygenated.

Succinate (amber).

Appendix to Hydrocarbons.

Asphaltum.—Bitumen, Asphalt, Mineral pitch.—Mixture of different hydrocarbons, part of which are oxygenated.

Following substances are closely related to asphaltum:

Grahamite, Albertite, Pianzite, Wollongongite.

Mineral Coal.—Made up of different kinds of hydrocarbons with perhaps, in some cases, free carbon.

- 1. Anthracite.
- Bituminous.
- 2. Coking.
- 3. Non-coking.
- 4. Cannel coal.
- 5. Torbanite.
- 6. Brown coal.
- 7. Earth brown coal.

(m). Blowpipe Characteristics.—The following important flame colorations result from the blowpipes: *Carminc*, from lithium compounds; *scarlet*, from strontium compounds; *yellowish red*, from calcium compounds; *yellow*, from sodium and all its salts; *yellowish green*, from barium compounds, molybdenum sulphide and oxide; *pure green*, from compounds of tellurium or thallium; *emerald green*, from most copper compounds with hydrochloric acid; *bluish green*, from phosphoric acid and phosphates with sulphuric acid; *feeble green*, from antimony or ammonium compounds; *whitish green*, from zinc; *light blue*, from arsenic, selenium and lead; *azure blue*, from copper chloride; *violet*, from potassium compounds.

Some of the Important Minerals.

THE GOLD MINERALS.

Tellurides.—Sylvanite, calaverite, krennerite.*Ores*.—Pyrite, arsenopyrite, pyrrhotite, and various sulphides, etc.

THE SILVER MINERALS.

Ordinary silver ores contain less than 1% of the silver compounds distributed through various minerals.

THE POTASSIUM MINERALS.

Chlorides.—Sylvite, carnallite, kainite. *Sulphates*.—Kalinite. *Nitrate*.—Nitre. The chlorides are the natural potash salts.

THE SODIUM MINERALS.

Chloride.—Halite. *Sulphate*.—Mirabilite. *Nitrate*.—Soda nitrate. *Carbonate*.—From $Na_2 CO_3$, $H Na CO_3$, $2H_2 O$.

THE LITHIUM MINERALS.

Used in medicine.

THE PLATINUM AND IRIIDIUM MINERALS.

Metals.—Platinum, iridosmine. *Arsenide*.—Sperryllite. *Purified platinum*.—Used in incandescent lamps, for electrical contact points, and in the so-called "oxidizing of silver." *Iridosmine*.—Pointing gold pens; phosphide of iridium is used for pointing tools and stylographic pens and for knife edges in the most delicate balances.

THE MERCURY MINERALS.

Sulphide.—Cinnabar. *Chloride*.—Calomel.

Uses.—Mercury is used in extraction of gold and silver from their ores; manufacture of vermillion; barometers, thermometers; silvering mirrors; medicine.

THE COPPER MINERALS.

Sulphides.—Chalcocite, bornite, chalcopyrite. *Sulpho-arsenite*.—Enargite. *Sulphoantimonite*.—Tetrahedrite. *Oxides*.—Cuprite, tenorite. *Basic chloride*.—Atacamite. *Sulphates*.—Chalcanthite. *Carbonates*.—Malachite, azurite. *Silicates*.—Chrysocolla, diastase.

Ores.—Chalcopyrite, bornite, native copper, cuprite, malachite, azurite.

Uses of copper.—Electrical work; alloys with zinc and tin, such as brass, yellow metal, bronze, bell metal, German silver.

THE IRON MINERALS.

Metal.—Iron. *Sulphides and arsenides*.—Pyrrhotite, pyrite, marcasite, arsenopyrite, leucopyrite. *Oxides*.—Magnetite, franklinite, hematite, menacanthite, turgite, goethite, melanterite. *Sulphates*.—Copiatite, melanterite. *Phosphates*.—Vivianite, triphylite. *Arsenates*.—Scorodite, pharmacosiderite. *Carbonate*.—Siderite. *Chromate*.—Chromite.

Ground for paint.—Limonite, hematite. *Used as iron ores*.—Hematite, limonite, magnetite, siderite. *For extracting sulphur*.—Pyrite, marcasite, pyrrhotite. *For arsenic*.—Arsenopyrite. *For chromium*.—Potassium bichromate, potassium chromate, ferro-chromium. *For tungsten*.—Wolframite, scheelite. *For gold and silver*.—Pyrite, arsenopyrite. *For nickel*.—Pyrrhotite.

THE CADMIUM MINERALS.

Sulphide.—Greenockite, is a yellow pigment of fixed color.

THE ZINC MINERALS.

Sulphide.—Sphalerate. *Oxide*.—Zincite. *Sulphate*.—Gostarite. *Carbonates*.—Smithsonite, hydrozincite. *Silicates*.—Willemite, Calamine.

Ores of zinc.—Spalerite, smithsonite, calamine, willemite, zincite. *Zinc oxide* also made from franklinite.

Uses of metallic zinc.—Galvanizing iron wire or sheets; manufacturing brass; sheet zinc, zinc dust. *Zinc white*, a paint, is zinc oxide ground in oil.

THE LEAD MINERALS.

Ores.—Galenite, cerussite. *Uses of lead*.—Manufacture of white lead, preparation of red lead, litharge, shot, lead pipe, sheet lead. *Alloys*.—With antimony for type, and, friction-bearings.

THE COBALT MINERALS.

Sulphides and arsenides.—Linnaeite, cobaltite, smaltite. *Arsenates*.—Erythrite.

Cobalt blue.—Cobalt and alumina compound. *Ainman's green*.—Compound of cobalt and zinc oxide.

THE NICKEL MINERALS.

Sulphides.—Millerite, pentlandite, gersdorffite. *Arsenides*.—Nicolite, chloanthite. *Arsenate*.—Annabergite. *Carbonate*.—Zaratite. *Silicate*.—Garnierite.

Alloyed with copper, iron and arsenic in making German silver; with copper (25% Ni and 75% Cu) in the five-cent piece; with steel in making nickel steel.

THE MANGANESE MINERALS.

Sulphide.—Alabandite. *Oxides*.—Braunite, hausmannite, pyrolusite, manganite, psilomelane. *Carbonate*.—Rhodochrosite, wad.

Alloys with iron, form: Spiegeleisen, ferro-manganese (for manufacture of steel). Used as manganese ores.—Pyrolusite, psilomelane.

THE CALCIUM MINERALS.

Limestone and marble are massive calcite and dolomite and are used largely in building construction. Limestone is used for hydraulic cements; and gypsum, for plaster of paris and wall plaster; also in paper making.

THE MAGNESIUM MINERALS.

Calcined magnesite is used as a lining for converters in the basic process for the manufacture of steel.

THE TIN MINERALS.

Sulphide.—Stannite. *Oxide*.—Cassiterite (ore of tin).

Uses of tin.—Tin plate (sheet iron coated with tin) for making cans, kitchen utensils, etc. *Alloy*.—Bronze, bell metal, pewter, solder, tin amalgam.

THE TITANIUM MINERALS.

Oxide of titanium used for glazing porcelain.

THE THORIUM MINERALS.

Oxide of thorium, thoria, constitutes about 99% (other 1% is cerium oxide) of the mantle of the Welsbach incandescent gas lamp.

THE ARSENIC MINERALS.

Sulphides.—Orpiment, realgar. *Sources*.—From arsenides and arseno-sulphides of iron, cobalt and copper. The white arsenic is a poisonous oxide, and is used in dyeing, medicine, sheep washing, calico printing, timber preservative, for fly paper, rat poisons and glass manufacture. Paris green is an arsenate of copper.

THE ANTIMONY MINERALS.

Sulphides.—Stibnite, kermesite. *Oxide*.—Valentinite.

Uses.—The sulphide is used in vulcanizing rubber.

THE BISMUTH MINERALS.

Uses.—Alloys with tin, lead and cadmium, *expand in cooling*.

THE SULPHUR AND TELLURIUM MINERALS.

Uses of Sulphur.—Manufacture of sulphuric acid, gunpowder, matches, rubber goods, bleaching, medicines, etc. Tellurium is closely related to sulphur in a chemical way.

THE URANIUM MINERALS.

A small quantity of uranium in steel increases the elasticity and hardness. *Ore*.—Uraninite (principal source of radium).

THE MOLYBDENUM MINERALS.

Sulphide.—Molybdenite. *Oxide*.—Molybdate.

Uses.—The metal is becoming important as an alloy with steel.

THE ALUMINUM MINERALS.

Ores.—Bauxite is the principal ore.

Uses of Aluminum.—Where lightness, strength and non-corrosiveness are desirable. It is replacing sheet copper and zinc and is used as bronze powder and alumina leaf for silvering letters and signs. It is replacing copper wire as electrical conductors. In metallurgy it is becoming important in welding pipes, rails in place, and steel castings. By adding less than 1% of aluminum to the melted metal it prevents blow-holes in castings of steel, copper and zinc.

THE BORON MINERALS.

Acid.—Sassolite. *Borates*.—Borax, ulexite, colemanite, boracite. Borax is used in welding; as a base of enamels on metal or porcelain; as a flux; as an antiseptic in packing meat; for powders, soaps, washing, dyeing, tanning.

THE HYDROGEN MINERALS.

Water is the most important, one-eighth of its volume being hydrogen. Hydrogen is present in combination with carbon forming marsh gas, petroleum, ozocerite, etc.

THE CARBON MINERALS.

Diamond and graphite are pure carbon. It is present in a large number of solid, liquid and gaseous compounds, as natural gas, petroleum, asphalt, bitumens, fossil resins, mineral waxes, coal. Carbon is present in all organic matter, entering with plant life from the carbon dioxide of the air; and exists to a large extent in natural gas.

THE SILICA MINERALS.

A.—Silica.

B.—Anhydrous Silicates.

- I. Disilicates and polysilicates.
- II. Metasilicates.
- III. Orthosilicates.
- IV. Subsilicates.

C.—Hydrous silicates.

- I. Zeolite Division.
- II. Mica Division.
- III. Serpentine and Talc Division.
- IV. Kaolin Division.

D.—Titano silicates.

Some of the Most Important Silicates:—

Granite.—Contains syenite, gneiss, basalt, diorite, andesite, which are compounds of silicates (usually three or more) and usually quartz, the feldspars and micas, pyroxene and amphibole.

Sandstone.—Made up of grains, mainly quartz, with perhaps feldspar, mica, or other mineral:

siliceous;
ferruginous;
calcareous;
argillaceous;

According to the nature of the cement which binds the grains together.

Bluestone.—Hard, durable, fine-grained sandstone, cemented with siliceous material.

Slate.—Hardened clay. Used mostly for roofing, sinks, blackboards.

Fibrous talc and compact talc.—Used in paper manufacture. The latter, soapstone, is very valuable because refractory, for use in furnaces, crucibles, sinks, baths, hearths, electric switch-boards, cooking utensils; also used in paints, slate pencils, crayon, gas tips, as a lubricant, and in soap making.

Mica.—Muscovite, phlogopite, biotite, have become of great importance as non-conductors in electrical apparatus; also for stove and furnace doors.

Asbestos.—This is fibrous amphibole and serpentine. It is used in the manufacture of incombustible paper, cloth, cement, boiler and steam-pipe covering and packing rope or yarn for valves.

Serpentine.—A marble.

Feldspar.—Crushed and mixed with kaolin in the manufacture of porcelain.

Quartz.—Used in the manufacture of sandpaper, glass, porcelain, hones, stones, oilstones and as a flux. Ground flint is used as a scouring agent in soaps.

Infusorial earth.—Calcined and made into water filters, polishing powders, soap filling and boiler and steam-pipe covering.

Kaolinite and clay.—Clay is decomposed feldspar and other silicates. It lies in beds composed partly of some hydrous aluminum silicates, as kaolinite, but is usually mixed with quartz, mica, undecomposed feldspar, oxides and sulphides of iron. The industry includes the manufacture of common brick, paving brick, fire-brick, hydraulic cement, earthenware, stoneware, porcelain, terra cotta, sewer pipe, drain tile.

Fuller's earth.—A clay used in refining and clarifying mineral oils.

Rocks and Rock-Formations (Lithology).

COMPOSITION.—The chemical elements which enter chiefly into the composition of the rocks may be classed as metallic and non-metallic, as follows:

Metallic (basic) elements.—Aluminum, magnesium, calcium, iron, sodium potassium.

Non-metallic (acidic) elements.—Oxygen, silicon, carbon, sulphur, phosphorus, chlorine, fluorine, hydrogen.

These are combined in various ways, forming the numerous minerals which compose the rocks. Table 4, following, gives a list of the principal rock-forming minerals, arranged as per E. S. Dana's classification. It will be seen that silica and the silicates play a most important part. The calcareous group of minerals comprise mainly the lime and magnesium carbonates, and the lime phosphates and sulphates, so that lime is a very important constituent. Iron is found plentifully in most of our heavier rocks, being associated principally with oxygen, sulphur and carbon. The hydro-carbons furnish a most useful group of substances to the engineer.

4.—PRINCIPAL ROCK-FORMING MINERALS.

GROUP.		Species.	Variety, etc.	Chemical Composition.	Hardness	Sp. Gr.	Color.	Remarks.
* Reference.	Name.							
1 II. B, 3, a.	Pyrite.	Pyrite.	(Firestone.)	FeS_2	5	5.0	Yellow.	Most abundant and widely distributed sulphide.
2 III. A.		Halite.	Rock salt.	$NaCl$	2.5	2.0	Light.	Found with calcite, gypsum, clay, sandstone.
3 V. α, A, 1, b.		Hematite.	(70% iron.)	FeO_3	6	5	Reddish.	Source of nearly all red and brown colors in rocks and soils.
4 V. α, A, 1, c.	Spinel.	Magnetite.	(72.4% iron.)	Fe_3O_4	6	5	Iron black.	Important iron ore; strongly magnetic.
5 V. α, A, 2.		Limonite.	(80% iron.)	$H_2Fe_2O_9$	5	4	Dark brown.	Source of yellow and light-brown colors in rocks and soils.
6 V. α C.		Quartz.	Rock crystal Chalcedony. Flint.	SiO_2 SiO_2 SiO_2	7 7 7	2.65 2.65 2.65	Light. Dark.	Prismatic and glassy. Translucent. Sub-translucent; contains carbon.
7 V. β, A, 1, 1° a.	Amphibole.	Pyroxene	(= Augite.)	$xSiO_3$	5.5	3.4	Light.	Found in limestone, dolomite, basalt, etc.
8 V. β, A, 1, 1° b	"		Hornblende.	$xSiO_3$	5.5	3.2	Black.	Black variety of amphibole.
9 V. β, A, 1, 2°, d.	Garnet.			Si, Fe , etc.	7	4.0	Brown.	Abundant in metamorphic rocks—schists and gneisses.
10 V. β, A, 1, 2°, f.	Epidote.	Epidote.		Si, Al, Co, Fe	6.5	3.4	Greenish.	Aluminum-iron-calcium silicate. Secondary in igneous and metamorphic rocks.
11 V. β, A, 1, 2°, k.	Mica.	Biotite.		Si, Al, K, Mg, Fe	2.5	2.9	Black.	Mg, K, Fe silicate; soft flexible layers.
12 " "	"	Muscovite.	(Common.)	Si, Al, K, H	2	2.85	Light.	Essential in granite, mica-schist, gneiss.

V, β , A, 1, 2°, w	Feldspar.	Plagioclase.	Albite. Labradorite.	{ Lime-soda feldspars. }	0	2.5 2.6	White. Dark gray.	Found in diorite. Plentiful in eruptive rocks.
"	"	Orthoclase.		Potash feldspar.	0	2.5	Light.	Occurs in granite, gneiss, sienite, etc.
V, β , A, 1, 3°, a.		Tourmaline.		{ Aluminum boro-silicate. }	7	3.0	Dark, etc.	Occurs in granite, gneiss, mica schists.
V, β , A, 1, 3°, c.		Staurolite.		H, Fe, Al, Si	7.53.5		Dark brown.	Accessory in metamor- phic slates and schists.
V, β , A, 2, III.	Talc.			H, Mg, Si	1	2.6	Light.	Granular massive varie- ties are soapstones.
"	Serpentine.	Serpentine.		H, Mg, Si	3.52.6		Greenish.	Tough, beautiful and dur- able stone.
"	Kaolinite.	Kaolinite.	China clay.	H, Si, Al	1	2.5		Decomposed granite— quartz, mica, feldspar.
"	Hydro-mica	Margarodite.		H, Si, Al, K	2.52.75		Greenish.	Similar in appearance to muscovite.
"	Chlorite.		(Schist.)	Si, Al, Mg, Fe	1.5		Dark green.	Composed mostly of chlorite.
V, β , F.		Gypsum.	Selenite.	H, Ca, S, O	2	2.3	Light.	The only rock-forming sulphate.
V, β , G.	Calcite.	Calcite.	(Anhydrous)	Ca CO ₃	3	2.7	White.	Crystalline-massive = limestone, marble, chalk.
"	"	Dolomite.	(Common.)	Ca, Mg, CO ₃	3.12.8		Light.	Similar to calcite.
"	"	"	(Brown spar)				Brown.	Massive; contains iron.

* As per classification of Minerals, Table 3, preceding.

The following Table of the common rocks is compiled mainly from notes of Prof. W. O. Crosby of the Mass. Inst. Tech., and shows the various groups of rocks grading one into another. Thus,

I.—Gravel, conglomerate.
 II.—Sand, sandstone, quartzite.
 III.—Clay, slate, (porcelainite.)
 IV.—Limestone, dolomite, magnesite, gypsum, rock-salt (phosphate rock).
 V.—Gneiss, (strat. syenite,) (strat. diorite,) (norite,) mica schist, hornblende schist, hornblende rock, (schorl schist.)
 VI.—(graphite schist,) talc schist, chlorite schist, greenschist, serpentinite.
 VII.—Granite, syenite, (diorite) diabase, rhyolite, trachyte, obsidian, petrosilex, felsite, andesite, basalt, tachylite, porphyrite, melaphyr.

5.—THE COMMON ROCKS.

No	Name.	Variety.	Composition.	Cementing Material.	Texture.	Remarks.
1	Beach Gravel.	Pebbles.	Quartz, feldspar, granite, etc	Clayey paste.		Rounded by action of waves.
2	Roxbury Puddingstone.	"	Consolidated pebbles, mud, sand.			Originally beach gravel.
3	Conglomerate.	"	Gravel and calcareous cement.	Carbonate of lime.		" " "
4	Limestone breccia.	"	Limestone pebbles and ferruginous cement.	Ferruginous.		Not brecciated (crushed and re-cemented) L.
5	Quartzose breccia.	Siliceous.	Quartz, red jasper, silica.	Silica.		Imperfectly cemented.
6	" puddingstone.	Vitreous.	do.	" (weak).		Looks like coarse granite.
7	"	"	Small grains do.	" (strong).		Deposited by strong currents.
8	Conglomerate.	Quartz.	Quartz, feldspar, schist.	Ferruginous.		From old rocks.
9	"	Mica.	Micaeous rocks.	arenaceous.		Grains sub-angular (not rounded.)
10	Beach sand.	Quartz.	Quartz—vitreous.	Argillaceous.		Bands parallel with stratification.
11	Sandstone.	"	Sand as No. 10, but cemented.	Iron oxide.	Banded.	Formed from old micaeous rocks.
12	"	Brownstone.	Quartz, feldspar, mica.	Ferruginous.		Larger proportion of mica than No. 12.
13	"	Brownstone.	do. (micaeous).		Shaly.	Formed in New Jersey: little or no mica.
14	"	"	Quartz, feldspar.		Fine grained.	Specks of iron oxide visible.
15	"	Freestone.	Quartz. (quartzose)		Friable.	Iron oxide not visible.
16	"	"	Quartz, greenish clay		"	Slightly stained with iron oxide.
17	"	"	Nearly pure quartz	Silica (weak).	"	Resembles granite.
18	"	Arkose.	Quartz, feldspar, mica. (feldspathic)			Argillaceous, micaeous, carbonaceous (dark).
19	"		Quartz, mica, clay.			No mica.
20	"	Brownstone.	Quartz, ferric oxide.	Ferruginous.	Homogeneous.	Splits easily.
21	"		Quartz, ferrous compounds.	"	"	Metamorphosed sandstone; vitreous.
22	"	Flagstone.	Quartz, mica, clay.	Argillaceous.	Fine.	
23	"	"	Quartz.	Silica.		
24	"	Quartzite.	Quartz.	Silica.		

1.—Formation of conglomerate, sandstone (and brownstone).

II.—Composition of various kinds of sandstone.

25	Clay.	Common.	Kaolin and quartz flour.	Soft earthy.	Forms the basis of nearly all kinds of slate.
26	Slate.	Normal.	Consolidated clay.		Brown bands = surface oxidation of iron oxide.
27	"	Sandy.	Consolidated clay, sand, mica.	Shaly.	A shaly, argillaceous sandstone.
28	"	Stratified.	Quartz, mica (sand), clay.	Laminated.	Hardness due to excess of quartz.
29	"	Massive.	Quartz.	Compact, stony.	From the celebrated trilobite quarry.
30	"		Brown clay and greenish gray sand.		Sedimentary under fluctuating currents.
31	"	Roosting.	Fine and homogeneous.	Laminated.	Perfect cleavage.
32	"	Highly metamorphic.	Semi-micaceous.		Imperfect cleavage.
33	Tufa.	Basaltic.	Basalt lava.	Porous	Ashen color.
34	Limestone.	Coquina.	Fragments of shells consolidated.	"	Imperfectly consolidated.
35	"		Coquina with clay filling.		Interstices filled with clay.
36	"	Tuffaceous.	Deposition of CaCO_3 on moss etc.	Tuffaceous.	Carbonate of lime and vegetable matter.
37	"	Calo tufa.	Travertine.	Compact.	Deposited at mouth of spring or river.
38	"	Coquina.	Finely ground corals, shells.	Porous.	Finely fragmental.
39	"	Earthy.	Calcite, fine clay (argillaceous).	Oolitic.	Uncrystalline; large proportion of clay.
40	"	Lithographic.	do.	Compact.	do.
41	"	"	do.		From an older formation than No. 40.
42	"	Argillaceous.	A calcareous slate.	Compact.	Carbonaceous (dark).
43	"	Hydraulic.	Calcite, clay, magnesite, silica.		When burned it makes a hydraulic cement.
44	"	Oolitic.	Nearly pure limestone.	Compact.	Crystalline near fossil remains.
45	"	Fossil.	Coral formation.	Crystalline.	Can be polished and used as a marble.
46	"	Crinoidal.	"	"	Same as No. 47, but colored by iron oxide.
47	"	"	"	"	Pure, uncolored, non-fossiliferous.
48	"	Marble.	Calcite.	Holocrystalline.	

III.—Formation of slate and limestone.

IV.—Composition of various kinds of limestone.

5.—THE COMMON ROCKS.—Continued.

No.	Name.	Variety.	Composition.	Cementing Material.	Texture.	Remarks.
49	Limestone.	Marble.	Pure calcite		Crystalline.	Typical marble; pinkish tint.
50	"	Crystalline.	Calcite; graphite, mica, iron.		Frangible.	Not suitable for building stone.
51	"	"	Calcite; serpentine, graphite, etc.			Serpentine is secondary after pyroxene.
52	"	Compact.	Calcite; chert (cryptocrystalline quartz).		Compact.	Chert is much harder than calcite.
53	Dolomite.	"	Dolomite.		"	Very little calcite.
54	"	Brecciated.	Dolomite; calcite, iron oxide.		Crystalline.	Partly brecciated; not conglomerate.
55	"	Crystalline.	Dolomite; tremolite (amphibole).		"	Contains but little calcite.
56	"	Coarsely "	Dolomite.		"	Coarse, pure dolomite.
57	"	"	Dolomite; calcite.		"	
58	Limestone.	Onyx Marble.	Nearly pure calcite; some iron		Banded.	Iron oxide and carbonate coloring.
59	Gypsum.		Gypsum.		Crys. to compact.	Does not contain calcite nor dolomite.
60	Halite.	Rock salt.	Sodium chloride; clay, iron oxide.		Cubic cleavage.	Common rock salt.
61	Gneiss.	Typical.	Feldspar, quartz, mica, hornblende.		Crys., banded.	The mica is mostly biotite.
62	"		Feldspar, quartz, biotite.		"	Little or no hornblende.
63	"		Quartz, feldspar; garnet.		Crys., laminated.	Almost binary; very little mica, no hornblende.
64	"	Typical, massive.	Quartz, feldspar, hornblende.		"	Abundance of feldspar makes it typical.
65	"	Granitoid.	Quartz, feldspar.		Crystalline.	Indistinctly laminated.
66	"	Muscovite.	Quartz, feldspar, mica.		Frangible, granular.	Mica is muscovite.
67	"	Granite (?).	Quartz, feldspar, mica (biotite).		Crystalline.	Shows some indications of stratification.
68	Mica, schist.	Normal.	Mica, quartz; garnet.		Crys.; schistose.	Mica (mostly muscovite); abundant.
69	"	{ Metamorphic }	Mica, quartz.			Granular aggregate.
70	"	{ sandstones. }	Mica, quartz.		Granular, friable.	Used for making scythe stones.
71	"	Typical.	Mica (muscovite) quartz; garnet.		Crys.; schistose.	Laminated.
72	"		Muscovite, biotite, quartz; garnet.		"	Contains prismatic staurolites.

VI.—Comparison of gneiss and mica schist.

V.—Comparison of limestone, marble, dolomite, gypsum, rock salt.

VII.—Composition of various kinds of schists.				VIII.—Comparison of granite, syenite and trap.			
		Ottrelite.	Mica, clay; ottrelite, garnet.			Crya.; schistose.	Illustrates change of argillaceous mica schist into meta.
73			Nearly pure quartzite; little mica.			"	Illustrates change of quartzose mica to quartzite and sandstone.
74			Quartz, hydra-mica.			"	
75	Schist.	Hydromica.	Quartz, hornblende.			"	
76	"	Hornblende.	Quartz, hornblende.			"	
77	"	"	Quartz, hornblende.			"	
78	"	Biotite.	Quartz, mica (biotite).			Crya.; laminated	Micaceous, greenish and soft.
79		Hornblende.	Pure hornblende rock.			Crystalline.	Much more hornblende than in No. 76.
80		Chlorite.	Nearly pure chlorite.			Crya.; schistose.	Very little hornblende, if any.
81	Schist.	"	Similar to but more massive than No. 80.			Crya.; schistose.	Has high specific gravity. Green color.
82	Talc schist.	Massive.	Soapstone.				Some hydromica, talc. Green color.
83	Greensand.	Typical.	Glaucanite; clay.				Not distinctly schistose.
84	Serpentine.	Impure.	Massive impure serpentine.			Compact.	Somewhat impure talc.
							Earthly granular mineral.
							Metamorphic eruptive rock.
85	Granite.	Micaceous.	Quartz, feldspar, mica.			Crystalline.	Mica is biotite and muscovite.
86	"	Rockport.	Quartz, feldspar, mica.			"	" " chiefly biotite.
87	"	"	Quartz, feldspar, hornblende mica.			"	Feldspar is orthoclase; mica is biotite.
88	"	Jonesboro.	do.			"	Feldspar (pink) crystals are double (= Carlsbad twins.)
89	"	"	do.			"	Feldspar (red) crystals are double (= Carlsbad twins.)
90	"	"	do.			Finely "	A few grains of epidote secondary after hornblende.
91	"	"	do.			" "	Some of the feldspar is pinkish.
92	"	"	do.			Crystalline.	Feldspar (orthoclase) red and green.
93	Syenite.	Typical.	Feldspar (orthoclase), hornblende.			"	No quartz. A little secondary biotite.
94	Trap.	(= Diabase.)	Feldspar (plagioclase), biotite, hornblende.			"	No quartz. Most of hornblende altered to biotite.
95	"	Compact.	Feldspar, hornblende.			"	Dark color; high specific gravity.
96	"		Feldspar (inc. plagioclase), hornblende.			Crya.; porphyritic	Plagioclase crystals.

5.—THE COMMON ROCKS.—Concluded.

No.	Name.	Variety.	Composition.	Cementing Material.	Texture.	Remarks.
97	Rhyolite.		Orthoclase, quartz, hornblende, biotite.		Crystalline.	Not a typical volcanic rock.
98	"	Typical.	Orthoclase, quartz, hornblende, biotite.		Imp. crys.	Orthoclase is sandline
99	Trachyte.	"	Sandline, hornblende, biotite.		Crys.; porphyritic	Some of sandline = Carlsbad twins. No quartz.
100	"		Feldspar (orthoclase ?)		Crystalline.	No quartz nor accessories
101	Obsidian.	Typical plain.	Orthoclase, etc.		Highly vitreous.	Acid volcanic glass; conchoidal fracture.
102	"	Banded.	do.		Vitreous, banded.	Alternate glassy and stony layers.
103	"	Spherulitic.	do.		Vit.; spherulitic.	
104	"	Pumice.	do.		Vit.; vesicular.	
105	Felsite.	= Petrosilex.	A completely devitrified obsidian. Acid.		Compact.	Red color due to oxidation.
106	"		Formerly banded obsidian.		Porphyritic.	Scattering crystals of feldspar.
107	"	Typical.	A basic or true felsite.		Finely banded.	Not porphyritic.
108	"	Quartz porphyry.	Porphyritic with quartz and feldspar.		Compact.	An acid felsite (petrosilex.)
109	"	Porphyritic.	Orthoclase, feldspar, hornblende.		"	Porphyritic feldspar; hornblende crystal.
110	"	"	do.		"	Reddened by oxidation.
111	Basalt.	Typical.	Augite, olivine, plagioclase, magnetite.		Crys.; vitreous.	Dark color; high specific gravity.
112	"		Augite, olivine, plagioclase.		Compact.	Augite and olivine, porphyritic.
113	"	Recent lava.	Leucite, augite, olivine, plagioclase.		Crys.; vesicular.	Leucite (crystals) replace plagioclase.
114	"		Vesicular basalt.		Compact.	Normally blended.
115	Tachylite.	Basaltic.	Olivine, plagioclase, etc.		"	Heavier and not so glassy as obsidian.
116	Melaphyre.	Greenstone.	Epidote, chlorite, quartz.		Comp.; crystalline.	Once an amorphous basalt like tachylite.
117	"	Compact.	Plagioclase, epidote, chlorite.		Amygdaloidal.	No. 113 with pores filled up.
118	"		do.		Comp.; brecciated.	Fragments cemented by secondary epidote.

NOTES ON PRECEDING TABLE.

Class I.—This group of rocks illustrates the formation, by various cementing processes, of pudding stone and conglomerate from ordinary beach pebbles; limestone breccia from limestone pebbles; conglomerate from old broken rocks; and sandstone from sand. Gravel consists of pebbles worn by the action of water to the size not smaller than a pea, while sand is the result of greater wear, the grains being minute. Shingle is larger than gravel. Quartz is a large constituent of gravel owing to its resistance to abrasion, hence old gravel is a durable material for building operations. Clay is mainly decomposed feldspathic rock in place. It is made up principally of silica and alumina, and contains also lime, magnesia, iron oxides, etc. As a cement it is called argillaceous.

The rock cements are mostly argillaceous (clayey), carbonate of lime (calcite), ferruginous (iron compounds), silica, arenaceous (sandy-quartz sand), iron oxide, etc. Very often they are a combination of these or perhaps consist of certain of their elements.

Cement gravel is partially formed rock composed of cemented gravel and sand. It occurs in various degrees of hardness and is often difficult to classify by the engineer, either as earth or rock. A separate classification is often preferred, as it is usually more easily broken up by blasting than by plowing; that is, powder is cheaper in some cases than the specified "six-mule team."

Class II.—This is a distinct group—sandstones. It is composed of stratified grains of sand cemented together. The nature of the cementing material determines largely the hardness or crushing strength of the sandstone, silica being superior to carbonate of lime or iron oxide in both strength and durability. Quartz is the principal constituent of sandstone; but mica, feldspar, hornblende and augite are often present. The sandstones lie midway between the conglomerates (pebble base) and the shales (indurated clay base). They may also be said to occupy a structural position between almost loose sand, in which there is little or no cementing material, and the consolidated, metamorphosed varieties which resemble granite. If the cementing material is carbonate of lime and very abundant, it gradates into limestone.

Of the varieties, quartzite is the hardest; arkose contains much feldspar; freestone, as its name implies, is easily worked; brownstone is an impure sandstone, rather soft, and found in Connecticut and New Jersey; flagstone is shaley and used for pavements, and includes the bluestone variety.

Class III.—Slate is a metamorphic clay or shale, produced by great heat and pressure. The old cleavage planes of the shale are changed to new cleavage planes in the slate, and when these are perfect it forms the typical roofing slate. Slate is quarried in Maine, Vermont, New York, Pennsylvania, Maryland, Georgia, Minnesota, California.

Classes IV. and V.—These two groups comprise mainly the limestones, marbles and dolomites. Under Class III. it was seen that a sandstone containing an abundance of calcareous (carbonate of lime) cement grades into limestone when the cementing material increases to such an extent that it really forms the base of the rock, the sand diminishing in quantity and becoming merely accessory, forming the impurities. Pure limestone is carbonate of lime, the cementing material of many other rocks. Limestone may contain also a small amount of carbonate of magnesia and such impurities as silica, alumina, ferric oxide, etc. When, however, the proportion of carbonate of magnesia increases to a considerable extent the limestone grades into dolomite. Further, if it contains a large amount of the above so-called impurities—silica and alumina—it becomes hydraulic limestone. Coquina and tufaceous limestones in Class III., and crinoidal limestone in Class IV, represent different sources of formation or origin.

Marble is a name formerly applied to all limestones of crystal and granular texture, capable of taking a polish; but it is now commercially used to apply to all limestones (even the non-crystalline) which can be polished.

Gypsum is composed of one-third lime (CaO), nearly one-half sulphuric acid (H_2SO_4), and one-fifth water. Alabaster is a pure white variety, while gypsum contains more or less earthy impurities. Plaster of paris is obtained by heating gypsum to above $127^{\circ}C.$ ($261^{\circ}F.$), driving off about one-seventh of the water of crystallization, and then grinding to powder.

Halite, No. 60, is sodium chloride (*Na Cl*) in the crystal form. Sodium chloride, common salt, plays a very important part in the manufacture of some high explosives.

Classes VI. and VII.—Gneiss is a name given to a class of metamorphic rocks composed essentially of the same elements as granite, namely, orthoclase, quartz and mica, with perhaps pyroxene, hornblende, etc. They may be either of igneous origin, like the granites and syenites, or of sedimentary origin, as the schists, presenting all gradations between these two classes. As they merge from the granitic to the schistose texture the feldspar disappears. Gneisses may be granitic (granite-gneiss), syenic (syenite-gneiss), hornblendic (hornblende-gneiss), etc., according to its composition.

Schist is a term applied to a metamorphic rock of slaty appearance, and of imperfect crystallization. Thus we have mica schist, hornblende schist, staurolitic schist, albite schist, etc. A slate is a schist of argillaceous character, forming a rather distinct class.

Soapstone, a magnesian silicate, is a talc schist and is very useful for hearthstones, sinks, etc.

Greensand or marl is composed mostly of glauconite (a silicate of iron and potash) and is used as a fertilizer.

Classes VIII., IX. and X.—These are distinctly igneous (eruptive) rocks, with more or less change in composition due to age of weathering.

Lava from an eruptive volcano is molten rock which subsequently hardens in cooling. Many attempts have been made to classify lava according to its composition or texture, but no satisfactory results have yet been attained. In density it varies from pumice, an extremely light, frothy, spongy form of obsidian (rhyolite) usually, to the heavy, compact basalt, which is usually the last of the lava flow.

Obsidian is a volcanic glass consisting approximately of silica (70 per cent), aluminum (12), calcium, potassium, sodium, iron, etc. The principal kinds of obsidian are rhyolite and trachyte.

Rhyolite has about the same chemical composition as granite, and from it, through weathering, etc., the latter is formed. Soda-rhyolites contain much sodium oxide; porphyritic-rhyolites are massive and compact. Felsite is a rhyolite which is not porphyritic.

Trachyte has about the same chemical composition as syenite, which, like granite, is formed through the action of weathering, changing slightly the chemical composition and, to a marked degree, the texture.

Basalt is a porphyritic rock of basaltic or columnar form. It is composed of hornblende, feldspar, augite, iron, and various other minerals. As it weathers very slowly it is synonymous with greenstone, trap, "basalt," etc., which comprise the so-called trap rocks. Melaphyr is a Tertiary basalt.

C.—BOTANICAL.

About three-eighths of the area of the United States, or 700,000,000 acres, is wooded; and of this, about 14 per cent comes under the United States Forest Service. The rapid depletion of our timber is a matter of grave concern, calling for abundant National and State reservations. The National forest reserves are situated usually at the heads of our tributary streams; serving, at the same time, to equalize the "run-off" of the precipitation, by retarding the melting of the snows in the spring of the year.

The following is a classification of the most important lumber trees of the United States and Canada:

—CLASSIFICATION OF IMPORTANT TREES.

	Height.	Dia.	Principal Localities.	Uses.
The PINES. Genus, <i>Pinus</i> .				
Soft Pines.				
...s. ...	60'-120'	3'-4'	Atlantic States.	Construction; cabinet work; masts; boxes.
...a P. ...	100'	4'-5'	Pacific Northwest.	Lumber in Montana and Idaho.
...rtiana)	200'-220'-300'	6'-10'	Oreg. to So. Calif., along W. Slopes Cascades, Sierra Nev.	Carpentry, doors, blinds, shingles.
...hite	40'-75'	2'-5'	E. slope Rocky Mts. from B.C. to Texas. Ariz and N. M.	Sap yields sugar. Lumber in Eastern Montana, Ariz., and N. M.

Pitch Pines.

...Bull	150'-230'	5'-8'	Mountain slopes, Neb. to Pacific; B. C. to Lower Cal.	Lumber, ties, fencing, fuel.
...ern P.	90'-120'	2'-2½'-3'	Belt 125 m. wide, Va. to Fla., W. to Miss. R. Isolated, Ala., La., Tex.	Most widely used in the East for heavy construction; * bridges, buildings, docks, masts, spars.
...eld P.	80'-100'	abt. 2'-3'	Coast: Cape May to Texas. Inland: Carolinas to Ark., La.	Lumber, h'vy cons.; docks, ships, cars, houses; ties.
... ..	75'-120'	2'-3'	Nor. U. S. and Canada, Me. to Minn., south to Penn.	Cons.; buildings, bridges, docks; masts, spars.
... ..	80'-100'-120'	3'-4'	Conn. to Fla., W. Va., E. Tenn.; Gulf States to E. La.; So. Missouri to E. Texas. Largest size W. of Miss. R.	Inferior to Longleaf P. for heavy construction. Wood is softer and more easily worked for carpentry.
...P. ...	100'	2½'-3'	So. Car. to So. Fla., and along Gulf to Pearl R., La.	Same uses as Longleaf pine.
... ..	-120'		So. Carolina to Miss.	Ties and fuel.

The LARCHES. Genus, *Larix*.

...ack ...	100'-250'	6'-8'	Columbia R. Basin; E'n Oreg., N'n Mont. and Idaho.	Ties, fence posts; durable; furniture and interior finish.
------------	-----------	-------	--	--

The SPRUCES (1). Genus, *Picea*.

... ..	70'-80'-100'	2'-3'	P. E. Island, N. Eng. N. Y., Alleg. Mts. to N. Carolina.	Lumber, paper pulp, flooring; sound'g bds. for musical instruments.
... ..	60'-70'-150'	-2'	N'n U. S., Canada and Alaska.	Inferior as lumber; superior for paper pulp.
... ..	-150'	4'-5'	Alberta, B. C., Mont., Idaho, Cascade Mts., Wash., Oreg.	Lumber, buildings, fuel, charcoal; bark tans leather.

6.—CLASSIFICATION OF IMPORTANT TREES.—Cont'd.

Species.	Height.	Dia.	Principal Localities.	Uses.
----------	---------	------	-----------------------	-------

The SPRUCES (1). Genus, *Piceo*.—(Continued.)

Sitka S., Tideland S. (<i>P. sitchensis</i>)	100'-200' -16'	3'-4'	Alaska, B. C., Wash., Oreg., to Mendocino Co., Cal.	Most imp. lum. Alaska; bldgs boats, fences, boxes, fuel.
---	-------------------	-------	---	---

The HEMLOCKS. Genus, *Tsuga*.

Hemlock (<i>T. canadensis</i>)	60'-70' -100'	2'-4'	N. Scotia to E'n Minn.; N. Y., N. Eng., Pa. to Ala.; Mich., Wis.	Lumber, build- ties; bark tan- leather.
Western H. (<i>T. heterophylla</i>)	100'-200' -250'	6'-10'	S. E'n Alaska to C. Mendocino; east to Mont. and Idaho.	Lumber for bu- lings; bark for ning.
Mountain H. (<i>T. mertensiana</i>)	70'-100' -150'	4'-5'	Alaska, B. C., Olym- pic Mts., Wash.; Cascades and Sier- ras.	Sometimes use lumber; bark tanning.

The SPRUCES (2). Genus, *Pseudotsuga*.

Douglas S., Red Fir. (<i>P. mucronata</i>)	100'-150' -300'	2'-3' -10'	S'n B. C., W'n Wash. and Oreg., N'n Cal., N. M., Ariz., Texas.	Known as Oreg. Pine, Wash. I. Superior for c- struction; lum.
---	--------------------	---------------	---	--

The FIRS. Genus, *Abies*.

White F. (<i>A. amabilis</i>)	70'-100' -200'	4'-6'	B. C., Olympic Mts.; Cascades, Oreg., Wash.	Largest and m- com. Fir in O- pic Mts. Int- finish.
White F. (<i>A. grandis</i>)	100'-250' -300'	2' -4'	Vancouver Id., Wash., N'n Oreg., Idaho, Mont.; N'n Cal.	Interior finish, packing boxe
Red F. "Larch." (<i>A. nobilis</i>)	150'-200' -250'	6'-8'	W'n Wash., Oreg.; N'n Cal. Cascades and Sierras.	Interior finish buildings, and packing cases

The REDWOODS. Genus, *Sequoia*.

Redwood (<i>S. sempervirens</i>)	200'-300' -325'	10'-15' -28'	Coast, S'n Oreg. to Monterey Co., Cal.	Lumber, build- shingles, pos- ties, wine-bu-
Big Tree (<i>S. wellingtonia</i>)	275'-325' -350'	20'-35'	Narrow area, W'n slope of Sierras. King's Riv.	Lumber, consti- tion; shingles fencing.

The ARBOR VITAEs. Genus, *Thuja*.

White Cedar, Arbor Vi- tae (<i>T. occidentalis</i>)	50'-60'	2'-3' -6'	N. Scotia to Manito- ba; central N. West; Allegheny Mts.	Fencing, ties, gles, tel. pole
Giant A.-V., Red Ced., Canoe Ced. (<i>T. plicata</i>)	150'-200'	bot- tom -15'	Coast, Alaska to C. Mendocino; Mts. E'ly to Idaho, Mont.	Finishing, hot doors, sashes cooperage.

The CYPRESSES. (1). Genus, *Cypressus*.

Monterey C. (<i>C. marocarpa</i>)	60'-70'	2'-3' -6'	Coast of Cal., south of Monterey Bay..	Hedges, wind brakes; shin
--	---------	--------------	---	------------------------------

6.—CLASSIFICATION OF IMPORTANT TREES.—Cont'd.

Species.	Height.	Dia.	Principal Localities.	Uses.
The CYPRESSES (2). Genus, <i>Chamaecyparis</i> .				
"White Cedar."..... (<i>C. thyoides</i> .)	70'-80'	2'-2½' -4'	Coast, Mass. to Fla., and west to Pearl Riv., Miss.	Finishing; shingles, cooperage, fencing, ties.
Sitka C. Yellow C..... (<i>C. nootkatensis</i> .)	100'-120'	5'-6'	S. W'n Alaska, B. C., Cascade Mts., Wash., Oreg.	Shipbuilding; interior finish; furniture.
Lawson Cypress..... (<i>C. lawsoniana</i> .)	150'-200'	-12'	Coast Mts. of Oregon and Cal.	Int. finish and flooring; ties, fencing; shipbuilding.

The CYPRESSES (3). Genus, *Taxodium*.

Bald Cypress..... (<i>T. distichum</i> .)	75'-150'	4'-5' -12'	Del. to Fla.; Gulf Coast to Tex.; Miss. Val. to Mo., Ind., Ill.	Lumber, flooring, shingles, cooperage, ties, fencing.
---	----------	---------------	--	---

The WALNUTS. Genus, *Juglans*.

Butternut, White W . . (<i>J. cinerea</i> .)	50'-100'	2'-3'	New Brunswick to Del. and to Dak.; Mid. West; Ga., Ala.	Cabinet work; interior finish.
Black W..... (<i>J. nigra</i> .)	75'-150'	4'-6'	Ontario to Fla.; west to Nebr. and Texas.	Cabinet work; interior finish; ship building.

The HICKORIES. Genus, *Hicoria*.

Shellbark H., Shagbark H..... (<i>H. ovata</i> .)	70'-90' -120'	3'-4'	Me. to Del. to Fla.; N'n Ala., Miss.; west to Minn., Neb.; south to Texas.	Agric. imp.; wagons and ax-handles.
Big Shellbark H..... (<i>H. lactiflora</i> .)	120'	-3'	Ohio Basin, Middle West, and South East.	Agric. imp.; wagons; ax-handles.
Pignut, White H..... (<i>H. glabra</i> .)	80'-90'	3'-4'	Me. to Fla., west thro Ont., Mich., Neb. South to Texas.	Agric. imp.; wagons; tools.
Mockernut H., Big Bud H..... (<i>H. alba</i> .)	50'-80' -100'	-3'	Ontario to Fla.; west to Kan. and Tex.	Agric. imp.; wagons; ax-handles.
Nutmeg H..... (<i>H. myristicifolia</i> .)	80'-100'	-2'	E'n S. Car.; Cen. Ala. Miss., to S'n Kan.	Lumber and fuel.
Pecan H..... (<i>H. pecan.</i> .)	100'-170'	4'-6'	S'n Ill., Ind., Ia.; Miss. Riv. States to Cen. Ala.	Fuel; valuable nut tree.
Bitternut H., Swamp H. (<i>H. minima</i> .)	60'-100'	2'-3'	Me. to Fla.; Ontario to Minn., Neb. and Tex.	Hoops and fuel.
Water H., Bitter Pecan. (<i>H. aquatica</i> .)	50'-80' -100'	-2'	Swamp regions, Va. to Tex.; north along Miss. R. to Ill.	Fencing, fuel.

The POPLARS. Genus, *Populus*.

Cottonwood..... (<i>P. deltoides</i> .)	60'-100' -150'	7'-8'	Quebec to N.W. Territory; south to Fla.; west to N.M.	Shelter and shade in prairie States.
Cottonwood..... (<i>P. fremontii</i> .)	100'	5'-6'	California. from Sacramento south; E'y to Col., Tex.	Shade tree; fuel.

6.—CLASSIFICATION OF IMPORTANT TREES.—Cont'd.

Species.	Height.	Dia.	Principal Localities.	Uses.
The POPLARS. Genus, <i>Populus</i> .—Continued.				
Aspen, Quaking Asp. (<i>P. tremuloides</i> .)	40'-100'	-3'	Newfoundland to Alaska; south to N. J.; west to Penn., Ky., Neb., Rocky Mts., Coast Range.	Shelter and shade; now rapidly spread over Rocky Mt. areas swept by fires.
Balm of Gilead (<i>P. balsamifera</i> .)	60'-100'	6'-7'	Newf'd'd to Alaska; S. to N. Y.; W. to Mich., Neb., Idaho.	Shade and shelter.
Black Cottonwood (<i>P. trichocarpa</i> .)	-200'	7'-8'	West coast, Alaska to S'n Cal.	Woodenware; staves of sugar barrels.
The WILLOWS. Genus, <i>Salix</i> .				
Black W. (<i>S. nigra</i> .)	40'-60'	-3'	Me. to Fla.; Rocky Mts.; Cal.	Borders of streams.
Golden Osier (<i>S. alba</i> .)	-120'	2'	Eastern N. America.	
The BIRCHES. Genus, <i>Betula</i> .				
Canoe B., Paper B. (<i>B. papyrifera</i> .)	60'-70'	2'-3'	Labrador to Alaska; south to Long Id.; Penn., Cent. Mich., Minn., Neb., Black Hills, Mont., N.W. Wash.	Letter paper; bark for canoes, and various camp articles.
Yellow B., Grey B. (<i>B. lutea</i> .)	-100'	3'-4'	Gulf of St. L. to Del., to N. Car., to Tenn. to Minn.	Furniture, boxes, wheel hubs, fuel.
The BEECHES. Genus, <i>Fagus</i> .				
Beech (<i>F. Americana</i> .)	70'-80'	3'-4'	N. Scotia to L. Huron; N'n Wis.; south to Fla., Mo. and Tex.	Chairs, shoe-lasts, plane-stocks, tool handles; fuel.
The CHESTNUTS. Genus, <i>Castanea</i> .				
Chestnut (<i>C. dentata</i> .)	60'-100'	3'-4'	S'n Me. to Mich.; south to Ind., Del.; to Ala., Miss.	Int. finish, furniture, ties, fencing, fuel.
Chinquapin (<i>C. pumila</i> .)	-50'	2'-3'	Penn. to Fla.; west to Ark. and Texas.	
The OAKS. Genus, <i>Quercus</i> .				
White Oaks.				
Pacific Post O., Oregon White O. (<i>Q. garryana</i> .)	60'-70'	2'-3'	Vancouver Id.; W'n Wash., Oreg., and Cal.	Cabinet work, wagons, ship building, cooperage, fuel.
Live O. (<i>Q. virginiana</i> .)	40'-75'	3'-4'	Coast and Islands, Va. to Fla.; Gulf and Lower Cal.	
White O. (<i>Q. alba</i> .)	60'-100'	3'-4'	S'n Me. to Fla.; west to Minn., Kan. and Tex.	Construction; ship-building, ties, int. finish, cabinet work.
Burr O., Mossy-Cup O. (<i>Q. macrocarpa</i> .)	70'-180'	6'-7'	Nova Scotia to Montana; s'th to Penn., Tenn. and Tex.	
Swamp O., Overcup O. (<i>Q. lyrata</i> .)	70'-100'	2'-3'	Maryland to Fla; west to Missouri and Tex.	Confoundered commercially with <i>Q. alba</i> , above.

6.—CLASSIFICATION OF IMPORTANT TREES.—Cont'd.

Species.	Height.	Dia.	Principal Localities.	Uses.
White Oaks.—Continued.				
Post O., Iron O..... (<i>Q. minor.</i>)	40'-50' -100'	2'-3'	Mass. to Fla.; west to Missouri and Tex.	Ties, fencing, fuel; cooperage.
Chestnut O., Tan-bark O (<i>Q. prinus.</i>)	60'-70' -100'	3'-4' -7'	Maine to Tenn.; Mts. in Ga. and Ala.	Cooperage, wheels, fencing, ties.
Yellow O..... (<i>Q. scumina.</i>)	80'-100' -160'	3'-4'	Vt. to Minn.; south to Ala. and Tex.	Cooperage, wheels, fencing, ties.
Swamp White O..... (<i>Q. plankanoides.</i>)	60'-70' -100'	2'-3' -9'	Me. to Great Lakes and Ia.; south to Md., Ga., Ky., Ark.	Cooperage, boat-building, fencing, ties, fuel.
Cow O., Basket O..... (<i>Q. michauxii.</i>)	60'-100'	3'-7'	N'n Del. to Fla.; west to Ill., Mo. and Texas.	Fencing, ties, fuel; bark for tanning.

Black Oaks.

Live O., Maul O., Gold-cup O..... (<i>Q. chrysolepis.</i>)	40'-50'	3'-5'	W'n slopes Sierras and Coast Mts., Oreg., and Cal.; Ariz., N. M.	Wagons and agric. imp.; most val. Oak on Pac. Coast.
Pin O., Swamp Spanish O..... (<i>Q. palustris.</i>)	70'-80' -120'	2'-3' -5'	Mass. to Del.; west to Wis. and Ark.	Cooperage; int. finish; shingles, clapboards.
Red O..... (<i>Q. rubra.</i>)	70'-80' -150'	3'-4'	N. Scotia to Minn.; south to Ga., Tenn. and Kan.	Interior finish; furniture; bark for tanning.
Scarlet O..... (<i>Q. coccinea.</i>)	70'-80'	2'-3'	Me. to Fla.; west to Ohio Val., Minn., Neb., Mo.	Interior finish; furniture.
Texas (Red) O..... (<i>Q. Texana.</i>)	50'-100' -200'	7'-8'	Iowa to Ind.; south to Fla. and Texas.	Lumber, Miss. Val., better than <i>Q. rubra.</i>
Black O., Yellow O..... (<i>Q. sciutina.</i>)	70'-80' -150'	3'-4'	Me. to Fla.; west to Minn., Kan., E'n Tex.	Fuel. Bark used in medicine, dyeing, tanning.
Spanish O..... (<i>Q. digitata.</i>)	70'-80'	2'-3'	N. J. to Fla.; west to Mo. and Tex.	Light construction, and fuel; bark for tanning.
Water O..... (<i>Q. nigra.</i>)	60'-80'	2'-3½'	Del. to Fla.; west thro Gulf States, Ky., Tenn., Ark. to Tex.	Fuel.
Willow O..... (<i>Q. phellos.</i>)	70'-80'	2'-3' -4'	N. Y. to Fla.; Gulf States to Tex.; N'y in Mo., Ky., Tenn.	Clapboards; fellics for wheels; some construction.
Laurel O., Shingle O.... (<i>Q. imbricaria.</i>)	50'-60' -100'	3' -4'	Penn. to Ga.; west to Nebr. and Ark.	Clapboards and shingles; some construction.

The ELMS. Genus, *Ulmus*.

White E., American E .. (<i>U. americana.</i>)	75'-125'	6'-11'	Newfoundland to Fla.; west to Rocky Mts.	Wheel hubs, saddle trees, flooring, cooperage.
Slippery E., Red E..... (<i>U. fulva.</i>)	60'-70'	2'	Ontario to Dak., Nebr.; south to Fla.; west to Tex.	Fencing, ties, wheel hubs, agric. implements.
Cedar E..... (<i>U. crassifolia.</i>)	-80'	2'-3'	S'n Ark., Miss. and Tex.	Fencing and fuel.

The SWEET GUMS. Genus, *Liquidambar*.

Sweet G., Blisted..... (<i>L. styraciflua.</i>)	80'-140'	4'-5'	Conn. to Mo.; south to Fla. and Tex.	Furniture, int. finish, shingles, fruit boxes, paving blocks, ties.
--	----------	-------	--------------------------------------	---

6.—CLASSIFICATION OF IMPORTANT TREES.—Concl'd.

Specials.	Height.	Dia.	Principal Localities.	Uses.
The MAPLES. Genus, <i>Acer</i>.				
Red M., Scarlet M., Swamp M.	80'-120'	3'-4½'	Eastern and Middle States, Lower Mississippi, Texas, New Brunswick to Dak.; south to Fla. and Oklohoma.	Tool handles, oars, furniture, wooden- ware; fuel.
(<i>A. rubrum</i> .) Silver M., Soft M.	90'-120'	3'-4'		Cheap furniture and flooring.
(<i>A. saccharinum</i> .) Oregon M., Broadleaf M. (<i>A. macrophyllum</i> .)	80'-100'	2'-3'	South Coast Alaska to San Diego, Cal.	Interior finish, fur- niture, ax- and broom-handles.
Sugar M., Rock M., Hard M.	75'-120'	2'-3'	Great Lakes to New- foundland. to Fla., to Neb., to Tex.	Buildings, flooring, furniture, boats, fuel.
(<i>A. saccharum</i> .) Black M., Black Sugar M. (<i>A. nigrum</i> .)	-80'	-3'	Dak. to Vt., to Va., Ky., Mo., Kan.	Buildings, flooring, furniture, boats, fuel.
The ASHES. Genus, <i>Fraxinus</i>.				
White A. (<i>F. americana</i> .)	-120'	5'-6'	N. Scotia to Fla.; west to Minn., Tex- as, Ohio R. Val.	Int. finish, stairs; tool handles, oars, furniture.
Black A. (<i>F. nigra</i> .)	80'-90'	1½'	Va. to Del. to Mani- toba, Ill., Mo., Kan.	Furniture, fencing, barrel hoops, cabi- net work.
Blue A. (<i>F. quadrangulata</i> .)	60'-70' 120'	2'-3'	Mich. to Mo., to Kan. to Ark.	Flooring, tool han- dles, vehicles.
Oregon A. (<i>F. oregona</i> .)	70'-80'	-4'	Coast, Puget Sound to San Francisco; Sierras.	Int. finish, furni- ture, wagons, cooperage, fuel.
Green A. (<i>F. lanceolata</i> .)	50'-60'	2'	L. Champl'n to Fla.; west to Ariz., Utah, Tex.	Int. finish, stairs; tool handles, oars, furniture.

INTERESTING FACTS ABOUT TREES.

Some of the Tallest Trees.—Big Tree (350 ft.), Redwood (325 ft.), Sugar Pine (300 ft.), Douglas Spruce (300 ft.), Western Hemlock (250 ft.), Western Larch (250 ft.).

Some of the Best Timber Trees.—Longleaf Pine, Douglas Spruce, White Pine, Norway Pine, Shortleaf Pine, Live Oak (*Q. virginiana*).

Some of the Best Lumber Trees.—All the timber trees make good lumber. In addition we may name: Most of the Pines, Spruces, Hemlocks, White Fir, Redwoods, Sitka Cypress, Lawson Cypress, some of the Walnuts and Hickories, many of the Oaks. Some of the Oaks, Ashes, Chestnuts, Maples, and Walnuts are used for interior finish.

Ages of Trees at Maturity.—White Pine, 250 yrs.; White Oak, 200 yrs.; Chestnut, 175 yrs.; Beech, 100 yrs.; Elms, 90 yrs.; White Ash, 80 yrs.; Birches, 50 yrs.

Relative Rapidity of Growth.—Silver Maple, White Elm, Red Maple, Sugar Maple, Chestnut, Red Oak, Pin Oak, Scarlet Oak, White Ash, White Oak.

Some Important Tree Products.—Tar, Rosin and Turpentine are obtained from the resin or sap of the longleaf pine. Pine tar is also obtained by the burning, or rather smouldering, of the limbs and knots of the longleaf pine. The dry distillation of woods produces wood vinegar (used for dyeing), acetic acid (which is made into vinegar), and wood alcohol. The latter may also be obtained from sawdust, and is destined to become a most valuable product for heating and power. Wood charcoal is also a valuable product. All are familiar with the products of the Balsam and the Sugar Maple. Wood pulp is used in making paper.

D.—ZOOLOGICAL.

Forenote.—So far as known there are about 350,000 living species of animals, and 50,000 extinct specimens, making a grand total of about 400,000. The latest and most logical classification of the animal world, by Parker and Haswell, comprises 12 grand divisions or Phyllums, arranged according to structure—beginning with the lowest forms, the Protozoans or unicellular animals, and ending with the highest forms, the Mammals with Man at the head of the scale. In the evolution of the species the lower forms of life have played an important part in the development of the higher, just as today the whole animal kingdom forms a valued adjunct to the development and uses of man.

Among the insects we have the *honey-bee*; the *silk-worm*; the cochineal, found on certain species of cactus, for useful and harmless *dye*; the lac for *shellac*; the galls of the gall-fly for ink, etc.

Many fishes, including the sword-fish, codfish, sunfish, etc., yield oil. Oil is also yielded by many reptiles, by the whale, walrus, manatee, etc.

The whale, narwhal and elephant furnish us with ivory; the seal, beaver, and other fur-bearing animals, with furs; the alligator, goat, and many quadrupeds, with skins for leather; the latter, also, with horns and tallow; the sheep, with wool; sea-fowl, with guano; etc., etc.

A considerable percentage of the animal world supplies us with food; and a few animals produce useful work.

The following classification is now recognized by scientists as the most logical that has ever been submitted.

7.—CLASSIFICATION OF ANIMALS.

(After Parker and Haswell.)

Class.	Subclass.	Phylum.
		a. Protozoa. (Unicellular animals.)
		I. Protozoa (Protozoans). One cell; or several cells of same kind.
		1. <i>Rhizopoda</i> (Amoeba, etc.). With retractile pseudopodia.
		2. <i>Mycetozoa</i> (Slimes). Terrestrial protozoa, plasmodial.
		3. <i>Mastigophora</i> . Without cilia, or sucking tentacles.
		4. <i>Sporozoa</i> . Without appendages; internal parasites.
		5. <i>Infusoria</i> . With sucking tentacles.
		β. Metazoa. (Multicellular animals.)
		II. Porifera (Sponges). Fixed; body-wall perforated, pores.
		1. <i>Porifera</i> .
		(a). <i>Calcarea</i> . With skeleton or calcareous spicules.
		(b). <i>Non-Calcarea</i> . Where skeleton exists, composed of siliceous spicules.
		III. Coelenterata (Polyps, etc.). Radial structure; digestive cavity lined.
		1. <i>Hydrozoa</i> (Hydroids, etc.). More than two rays; single cavity.
		2. <i>Scyphozoa</i> (Jellyfishes). Many radii; cavity divided by radial partitions.
		3. <i>Actinozoa</i> . Colonies or attached individuals.
		(a). <i>Zoantharia</i> (Sea-Anemones, Corals, etc.). Numerous tentacles, usually in 5's.
		(b). <i>Alcyonaria</i> (Sea-Fans, Red Corals, etc.). Eight tentacles.
		4. <i>Ctenophora</i> . With two radii, and rows of sucking tentacles.
		IV. Platyhelminthes (Flatworms). Body composed of loose cells.
		1. <i>Turbellaria</i> (Planarians). Body covered with cilia; one opening to alimentary tract.
		2. <i>Trematoda</i> (Flukes). Parasitic, unsegmented; adult without cilia.
		3. <i>Cestoda</i> (Tapeworms). Without mouth or alimentary canal.
		4. <i>Nemertinea</i> . Carnivorous and aquatic; with mouth, arms, and food canal.
		(a). <i>Palaeonemertinea</i> .
		(b). <i>Schisonemertea</i> .
		(c). <i>Hoploneemertea</i> .

7.—CLASSIFICATION OF ANIMALS.—Cont'd.

Class.	Subclass.	Phylum.
--------	-----------	---------

V. *Nemathelminthes* (Round worms). Usually—mouth, arms, alimentary tract.

1. *Nematoda* (Threadworms). With intestinal canal; parasitic.
2. *Acanthocephala*. Parasitic; no mouth or intestines.
3. *Chaetognatha* (Arrow worms). Developed nervous system; spiny.

VI. *Trochelminthes* (Wheel-animalcules). Larva in trochosphere form.

1. *Rotifera*. Microscopic.
2. *Dinophilea*. Minute; with 5 to 8 segments, usually ciliated.
3. *Gastrotricha*. Minute; ciliated on ventral surface.

VII. *Molluscoida* (Sea-Mats and Brachiopods). Aquatic.

1. *Polysoa* (Bryozoans). Form colonies connected by one organic substance.
 - (a). *Ectoprocta*. Anus, external.
 - (b). *Endoprocta*. Anus, internal; bud, forming colonies.
2. *Phoronida*. Worm-like; born from ova, not by buds.
3. *Brachiopoda* (Lamp-shells). Body enc. in shell of two valves, usually on a stalk.

VIII. *Echinodermata* (Echinoderms). With intestinal walls.

1. *Asteroidea* (Starfish). Star-shaped; furrows under the arms.
2. *Ophiuroidea* (Brittle Stars). Arms not grooved.
3. *Echinoidea* (Sea-Urchins). Body, globular; armless.
4. *Holothuroidea* (Trepangs). Worm-like; with tentacles about mouth.
5. *Crinoidea* (Crinoides). Sessile; with cup-shaped body.
6. *Cystoidea* (Fossil). Globular and stalked (sessile).
7. *Blastoidea* (Fossil). Ovate; stalked.

IX. *Annulata* (Worms). Bilaterally segmented; without jointed legs.

1. *Chaetopoda* (Annelids). Composed of series of metameres, bearing cirri.
 - (a) *Polychaeta* (Marine Annelids). Sexes distinct; ovaries and testes, many.
 - (b) *Oligochaeta* (Fresh water and terrestrial). Sexes united; ovaries and testes, few.
2. *Myzostomida* (Crinoides). Unsegmented.
3. *Gephyrea* (Marine). Sessile; adult, without external segmentation.
4. *Archi-Annelida* (Often Parasitic). Minute; marine, segmented (faintly).
5. *Hirundinea* (Leeches). With ventral suckers.

X. *Arthropoda* (Insects, Crustaceans, etc.). Symmetrical, segmented.

1. *Crustacea* (Crustaceans). Aquatic, gill bearing; two pairs antennae, usually.
 - (a) *Entomostraca* (Water-Fleas, etc.). Varied number of appendages.
 - (b). *Malacostraca* (Crabs, Crayfish, etc.). With 19 pairs of appendages.
2. *Trilobita* (Extinct Trilobites). With head, thorax and abdomen.
3. *Onychophora* (Peripatus). With series of short walking appendages.
4. *Myriapoda* (Centipedes and Millipedes). Segments, each with 1 or 2 pairs of legs.
5. *Insecta* (Insects). With six thoracic legs, and usually with wings.
6. *Arachnida* (Spiders, Scorpions, etc.). Air-breathing; without antennae.

7.—CLASSIFICATION OF ANIMALS.—Concluded.

- | Class. | Subclass. | Subphylum. | Phylum. |
|--|--------------------|------------|---|
| <p>XI. Mollusca (Mollusks). Unsegmented; muscular locomotion.</p> | | | |
| 1. | | | <i>Pelecypoda</i> (Bivalves). Gills leaf-like; two-valved shell. |
| 2. | | | <i>Amphineura</i> (Chitons). Symmetrical bi-laterally; anus at end of body. |
| 3. | | | <i>Gastropoda</i> (Gastropods). Unsym. body; shell (if any) univalve. |
| | | | (a). <i>Streptoneura</i> (Limpets, Whelks, etc.). Visceral commissures like a figure 8. |
| | | | (b). <i>Enthyneura</i> (Pulmonates Nudibranchs, etc.). Vis. com. not like a figure 8. |
| 4. | | | <i>Scaphopoda</i> (Marine). Mouth-lobes formed into a tube. |
| | | | (a). <i>Scaphopoda</i> (Tusk-shells.) |
| | | | (b). <i>Rhodops</i> . Minute; no shell; with sucking tentacles. |
| 5. | | | <i>Cephalopoda</i> (Cuttle-fish). Mouth surrounded by arms; foot funnel-shaped. |
| | | | (a). <i>Dibranchiata</i> (Squids, Octopods). Two sym. branchiae; tubular funnel. |
| | | | (b). <i>Tetrabranchiata</i> (Nautilus, Ammonites). Four branchiae; multi-ocular shell. |
| <p>XII. Chordata (Chordates). Animals having a notochord.</p> | | | |
| 1. | (A). | | <i>Adelochorda</i> (Balanoglossus, etc.). Marine; with notochord as larvae. |
| 2. | (B). | | <i>Urochorda</i> (Ascidians). Marine; having a notochord when larvae. |
| | (C). | | <i>Vertebrata</i> (Vertebrates). Sym. bilaterally; having a backbone. |
| | (I). | | <i>Acrania</i> (Branchiostomidae, Amphioxus, etc.). Without a head. |
| | (II). | | <i>Craniata</i> (Fishes, Reptiles, Birds, Mammals). |
| 1. | | | <i>Cyclostomata</i> (Lampreys). Eel-like, without lower jaw; mouth, suctorial. |
| 2. | | | <i>Pisces</i> (Fishes). Aquatic; persistent gills, paired fins. |
| | (a). | | <i>Elasmobranchii</i> (Sharks and Rays). Cartilaginous skeleton; cranium not ossified. |
| | (b). | | <i>Holocephali</i> (Chimaeras). Cartilaginous; four pairs of gill slits. |
| | (c). | | <i>Teleostomi</i> (Sturgeons and ordinary Fish). |
| | (d). | | <i>Dipnoi</i> (Lungfishes). Fish-like animals with apparatus for breathing. |
| | (e). | | <i>Ostracodermi</i> (Cephalaspis, etc.). |
| 3. | | | <i>Amphibia</i> (Amphibians). With gills when leavae, lungs when adult. 5-toed feet. |
| 4. | | | <i>Reptilia</i> (Reptiles). Air-breathing; horny epidermal skeleton of scales. |
| 5. | | | <i>Aves</i> (Birds). Clothed with feathers. |
| | (a). | | <i>Archaeornithes</i> (Archaeopteryx). With prolonged tail of many vertebrae. |
| | (b). | | <i>Neornithes</i> (Modern Birds). Tail vertebrae compacted. |
| 6. | | | <i>Mammalia</i> (Mammals). Suckle their young; clothed with hair, more or less. |
| | (a). | | <i>Prototheria</i> (Didelphia). Mammals with oviducts separated. |
| | (b). | | <i>Theria</i> (Monodelphia). Mammals with oviducts more or less united. |
| | (b ₁). | | <i>Metatheria</i> (Marsupials). Rudimentary birth; sheltered in pouch. |
| | (b ₂). | | <i>Eutheria</i> (higher Mammals). Born in uterus; no pouch. |

18.—EXPLOSIVES.

An explosive is a mixture which, under certain disturbing influences, enters into rapid chemical reaction, forming expansive gases and evolving much heat. The substances mixed may be solid or liquid. Explosives may be classified according to the nature of the mixture, whether *mechanical* or *chemical*.

(a). MECHANICAL MIXTURES.

In mechanical mixtures the component elements remain intact until a high temperature is reached, when they chemically react and pass off as gases (mostly), causing the explosion.

Nitrate Mixtures.—This class comprises the mixture of a nitrate, embodying oxygen, with some base yielding carbon and usually containing sulphur. The explosion occurs when the oxygen leaves the nitrate and combines with the carbon, having a greater affinity for the latter. Gunpowder is typical of this class.

Gunpowder.—This is the oldest and one of the most common of explosives. It consists of a mixture of saltpetre (=nitre=potassium nitrate = KNO_3), charcoal (=carbon) and sulphur in various proportions according to the nature of the explosion desired. The black powder, formerly used almost exclusively in U. S. ordnance, was composed of 75 parts saltpetre, 15 parts charcoal and 10 parts sulphur; while the brown or sporting powder contains much more charcoal and considerably less sulphur, the proportions being, 79 parts saltpetre, 19 parts charcoal and 3 parts sulphur. These are now being superseded by the smokeless powder.

Blasting Powder.—This is made slower acting than the gunpowder by reducing the proportion of saltpetre to 66 parts, charcoal forming 15 parts, and sulphur 19 parts. Sodium nitrate or Chili saltpetre is now commonly used instead of the more expensive potassium nitrate.

Assuming the weight of powder at 62.5 lbs. per cu. ft. (spec. grav. = unity), the following table gives the weight of powder in a hole one ft. deep and of various diameters:

1.—WEIGHT OF POWDER IN A HOLE ONE FOOT DEEP.

Diam. Ins.	Weight. Lbs.	Weight (Avoir.) Lbs. Ozs.	Diam. Ins.	Weight. Lbs.	Weight (Avoir.) Lbs. Ozs.
$\frac{1}{8}$	.0852	0 — 1.4	$2\frac{1}{2}$	2.131	2 — 2.1
$\frac{1}{4}$	.1332	0 — 2.1	3	3.068	3 — 1.1
$\frac{3}{8}$	.1917	0 — 3.1	$3\frac{1}{2}$	4.176	4 — 2.8
$\frac{1}{2}$	.2610	0 — 4.2	4	5.454	5 — 7.3
$\frac{5}{8}$	.3409	0 — 5.5	$4\frac{1}{2}$	6.903	6 — 14.5
$\frac{3}{4}$	.5326	0 — 8.5	5	8.522	8 — 8.4
$1\frac{1}{4}$	.7670	0 — 12.3	$5\frac{1}{2}$	10.312	10 — 5.0
$1\frac{1}{2}$	1.044	1 — 0.7	6	12.27	12 — 4.4
2	1.364	1 — 5.8	$6\frac{1}{2}$	14.40	14 — 6.4

Note.—Weight in lbs. = $0.3409 \times (\text{diam. of hole in ins.})^2$; therefore it is proportional to the square of the diameter of the hole.

Other Nitrate Explosive Mixtures.—The following mixtures are analogous to gunpowder in exploding at high temperatures:

Amide.—Ammonium nitrate, potassium nitrate, charcoal.

Azotine.—Sodium nitrate (69), carbon (15), sulphur (12), petroleum (4).

Carbo-azotine.—Potassium nitrate (61), soot (26), sulphur (14).

Dioezime.—Potassium nitrate (50), sodium nitrate (25), sulphur (12), hard sawdust (13).

Joknite.—Potassium nitrate (75), sulphur (10), lignite (19), sodium picrate (3), potassium chlorate (2).

Petralite.—Potassium nitrate (64), charcoal (30), crude antimony (6).

Pyrolite.—Potassium nitrate (51), sodium nitrate (16), sulphur (20), sawdust (11), charcoal (2).

Chlorate Explosive Mixtures.—Potassium chlorate is a constituent in each of the following explosives, which are considered rather unsafe on account of spontaneous or premature reaction:

Asphalite.—Potassium chlorate (54), potassium nitrate and sulphate (4), bran (42).

Eckhardt P.—Potassium chlorate, cream of tartar, powdered nutgalls, tannin.

Fontaine P.—Potassium chlorate, potassium picrate.

Horseley P.—Potassium chlorate (6), nutgalls (1), charcoal (1), nitroglycerin (72). (This is a dynamite.)

Michalowski Blasting P.—Potassium chlorate (50), manganese dioxide (5), bran (45).

Oriental P.—Potassium nitrate and crude gamboze, potassium chlorate.

Pyronome.—Potassium nitrate (69), sulphur (9), charcoal (10), antimony (8), potassium chlorate (5), rye flour (4), potassium chromate.

Rackarock.—Potassium chlorate (79), mono-nitrobenzine (21). Fresh mixed.

(b). CHEMICAL COMPOUNDS.

Nitro-substitution Explosive Mixtures.—The following are examples of nitric acid treatment of the hydrocarbons, producing compounds which at high temperatures become unstable:

Ammonites.—Ammonium nitrate (88), di-nitro naphthalin (12).

Bellite.—Ammonium nitrate (5), meta-di-nitrobenzine (1), potassium nitrate.

Borlinetto P.—Picric acid (10), sodium (10), potassium chromate (8).

Extralite.—Ammonium nitrate, potassium chlorate, naphthalin.

Jovite.—Nitro-naphthalin, nitro-phenol, sodium nitrate.

Roburite.—Ammonium nitrate, chlorinated di-nitrobenzine.

Romite.—Ammonium nitrate, potassium chlorate, naphthalin.

Securite.—Ammonium nitrate, di-nitrobenzine.

Volney P.—Potassium nitrate, sulphur, nitro-naphthalin.

Nitric Acid Compounds.—When certain vegetable tissues, called cellulose, notably cotton, are treated with nitric acid the resulting cellulose nitrate is a very high explosive. The stronger treatments produce *gun-cotton* and the weaker, *pyroxylin*. Similarly, when the animal compounds *gelatin*, or *glycerine*, are treated with nitric acid there results *nitroglycerin*, a most powerful explosive. *Dynamite* consists of some absorbent soaked with nitroglycerin to protect the latter from decomposition and premature explosion.

Guncotton.—This is made by soaking cotton, or other form of cellulose, in nitric acid (one part) and sulphuric acid (three parts) for about a day, and then thoroughly washing. The resulting product is from 60 to 85 per cent heavier than the cellulose, depending upon the proportion and strengths of the acids and the general treatment. It is the safest explosive known in general handling and shipment. It is exploded by percussion when confined and highly compressed, but if ignited burns quietly without explosion.

Guncotton is used as an agent in various mixtures containing nitrates of which the following are examples:

Glyoxiline.—Guncotton, saltpetre, nitroglycerin,—in form of pellets.

Potentile.—Guncotton, saltpetre,—in form of cartridges.

Tonite.—Guncotton, barium nitrate,—in form of cartridges.

Detonation.—In our classification of the various explosives under the two headings, Mechanical Mixtures and Chemical Compounds, we are confronted with the great natural law of gradation, which is universal. For instance, there are some animate objects which the naturalist is unable to classify distinctly as plants or animals, bordering on the division line and having some of the common attributes of both great orders in nature. So with explosives. Up to 1864, when Alfred Nobel, a Swedish engineer, began to put some of the higher explosives to practical use, the great principle of "detonation" or instantaneous explosion by "shock" was but vaguely known. His investigations with nitroglycerin led to the discovery that many explosives heretofore treated by ordinary combustion were far more powerful when subjected to "percussion," which converted the substance *immediately* into gas. In his experiments with nitroglycerin he used a percussion cap charged with fulminate of mercury as an initiatory explosive. Detonation is essential in the higher class of explosives as guncotton, nitroglycerin, dynamite, etc.

The following are some of the guncotton preparations resulting from Nobel's discovery:

Blasting gelatin.—Guncotton absorbed in nitroglycerin.

Gelatin dynamite.—Blasting gelatin and an absorbent.

Forcite.—Blasting gelatin (50), absorbent (50).

Gelignite.—Blasting gelatin (65), absorbent (35).

Smokeless Powders contain guncotton, nitrate, carbonate, nitroglycerin, and various other substances of like nature. The product is a horn-like substance, which is cut into chords or grains.

Nitroglycerin.—To the engineer, this is one of the most useful and most powerful explosive agents. It is prepared by treating glycerin with strong nitric and sulphuric acids, producing the chemical compound, $C_3H_5N_3O_9$. In its pure liquid form it burns quietly, producing carbon dioxide, hydrogen nitrogen and water. But when gradually heated to 180°C . or when subjected to violent percussion it explodes, developing gases from 1200 to 1400 times the volume of the liquid, which in turn are further expanded by the great amount of heat evolved, to about 10,000 times the original bulk. Nitroglycerin when mixed with infusorial earth as an (inert) absorbent forms *dynamite*, which is sold under various trade names.

Dynamite.—As the liquid nitroglycerin is liable to explode by heat or decomposition, it is rendered safer by being combined with some protecting absorbent. The absorbent may be *inert* or *active*, naturally dividing the dynamite into two classes. The second class comprises by far the most important, as follows:

Atlas P.—Nitroglycerin (75), wood fibre (21), sodium nitrate (2), magnesium carbonate (2), Also lower grades.

Carbonite.—Nitroglycerin (25), wood dust (40), sodium nitrate (34), sodium carbonate (1).

Dualin.—Nitroglycerin (40), wood dust (30), potassium nitrate (20).

Giant P.—Nitroglycerin (40), resin (8), kieselguhr (8), sulphur (6), sodium nitrate (40).

Hercules P.—Nitroglycerin (40), wood fibre (11), sodium nitrate (45), sodium chloride (1), magnesium carbonate (1).

Judson P.—Nitroglycerin (5), cannel coal (15), sulphur (16), sodium nitrate (64).

Lithofracteur.—Nitroglycerin (54), kieselguhr (17), sulphur (7), barium nitrate (15), wood dust (2), manganese (2), soda (2), bran (1).

Meganite.—Nitroglycerin (60), nitrated wool and vegetable ivory (20), sodium nitrate (20).

Rhexite.—Nitroglycerin (64), decomposed wood (11), wood dust (7), sodium nitrate (18).

Safety nitro P.—Nitroglycerin (69), wood fibre (13), sodium nitrate (18).

Stonite.—Nitroglycerin (68), wood dust (4), kieselguhr (20), potassium nitrate (8).

Vigorite.—Nitroglycerin (68), kieselguhr (20), potassium nitrate (7), carbonate, etc. (5).

Vulcan P.—Nitroglycerin (30), charcoal (11), sulphur (7), sodium nitrate (52).

Unmixed Explosives.—There is a certain class of explosives called *Panclastites*, consisting of two ingredients which separately are inexplusive but when mixed are considered fully as powerful as dynamite. They are shipped separately and mixed at the site when needed for use. The principal ingredients of the mixture are nitrogen tetroxide and carbon disulphide. They are not generally recommended for ordinary use by the class of men usually employed in blasting.

Percussion Caps.—Fulminate of mercury enters into the composition used for percussion caps and electric fuses employed in detonating charges of dynamite in blasting operations. It is prepared by adding alcohol to a nitric acid solution of mercury.

(c). The Handling and Use of Dynamite.

Dynamite as invented by Noebel in 1867 consisted of nitroglycerin absorbed by a porous, inert solid. The best absorbent was found to be a siliceous, infusorial earth known as *kieselguhr*, obtained in Hanover, Germany. When dried it is an impalpable, white powder of cellular structure, and is capable of absorbing three times its weight of nitroglycerin, giving the resultant dynamite the appearance and consistency of heavy brown sugar. Coupled with its absorbent, nitroglycerin is thus, in the form of dynamite, free from the danger of spontaneous explosion, and detonation from shocks of a moderate nature. In the loose powdered form, dynamite loses none of its explosive properties when exposed to natural temperatures; i.e., it explodes readily by the action of the fulminating mercury primer or cap. On the other hand, when the powder is compressed into cartridges and the temperature is reduced to between 50° and 42° F., it freezes and, like frozen nitroglycerin, is inexplusive. It loses only a small percentage of its explosive power on being saturated with water, hence its great value in submarine work. If unconfined and ignited by a flame (350° F.) it burns freely and quietly without explosion.

Dynamite is usually compressed in sticks or cylinders called cartridges, varying from $\frac{1}{4}$ to 2 ins. in dia. and about 8 ins. long, more or less; or they are sold in any size and length ordered. The sticks are wrapped separately in paper, and packed in boxes, in layers cushioned with sawdust; usually 50 lbs., or 25 lbs., to the box.

In "freezing" weather these cartridges have to be "thawed" out. The term "freezing" applies to any temperature that chills the dynamite, usually in the neighborhood of 45° F., sometimes lower and sometimes higher, depending upon the grade, the quality of the absorbent, and the nature of the exposure. The "thawing" of dynamite consists in slightly warming it to take off the chill. It sometimes requires a temperature of 50° or 60° F. to do this effectively, and it must not be allowed to chill again while being carried to the drill holes and loaded. The usual method of thawing dynamite is by a small out-door fire, but the disadvantages of this plan are: (1) waste of time in thawing, (2) greater or less danger attached to it, (3) inefficiency of thorough thawing so that the dynamite will explode with the greatest effect. In a pamphlet "Thawing Dynamite" published by the Aetna Powder Co., of Chicago, is an illustration of a Thaw House about 7x10 ft., fitted with steam coils and shelves for thawing. The shelves have a capacity of about 500 lbs. of dynamite, and about 1000 lbs. more can be stored in the house in boxes. The special caution for sweeping and cleaning merits careful attention.

In preparing the charge, the fulminating cap, to which the safety fuse has been attached, is inserted in the top of the cartridge, the neck of which is tied around the fuse with a string, and the charge placed in the hole and fired. If an electric blasting machine is used, a special cap is required.

Many of the dynamites are put up in two grades, No. 1, and No. 2, the former containing as high as 75% N.-G. Some of the powders are furnished in several grades, ranging from 75 down to 20% N.-G. In ordering dynamite it is necessary to state the percentage of nitroglycerin required, whether 30, 40, 50, 60, 75%, unless the name of the desired brand is known.

2.—SOME OF THE MOST COMMON COMMERCIAL DYNAMITES.

(Note.—The percentages of nitroglycerin are shown in parentheses.)

Aetna powder, No. 1 (65), No. 2 XX (50), No. 2 (40), No. 3 X (30), No. 4 X (25), No. 5 (15).

Atlas powder, A (75), B + (60), B (50), C + (45), C (40), D + (30), D (30), E + (25).

E (20), F + (15).

Colonia powder (40).

Carbonite (25).

Dualin (40 to 50).

A List of Permissible Explosives for Use in Coal Mines.—Following brands, tested prior to Oct. 1, 1900: Aetna coal powder A, AA, B, C; Blount No. 1; Black Diamond Nos. 3, 4; Carbonite Nos. 1, 2, 3, 1-L, 2-L, F.; Coalite Nos. 1, 2-D; Coal Special Nos. 1, 2; Collier dynamite Nos. 2, 4, 5; Gyant A low-flame dynamite, C low-flame dynamite; Masur M. L. F.; Meteor dynamite; Mine-ite A, B; Manobel; Tunnelite Nos. 5, 6, 7.

19.—PRESERVATIVES.

PAINTS.

A paint consists of a pigment, vehicle, drier, and (usually) solvent. Sometimes the pigment is ground alone and then mixed with the vehicle and drier but usually they are ground together, and sealed in kegs or cans for shipment.

Pigments.—The following are the most important to the engineer:

White lead, consisting of a mixture of lead hydrate and lead carbonate, is universally employed for white paint. It is often adulterated, however, with heavyspar, gypsum, chalk, clay, sulphate of lead, etc., which renders it more or less inferior.

White zinc or zinc oxide is used for white paint; often adulterated with heavyspar.

Lampblack (mainly carbon) is one of the best pigments for black paint and for printer's ink. It is obtained by burning substances rich in carbon, with a low flame, that is, to incomplete combustion, so the carbon will not be burned. For this purpose resin, ozokerite, the by-product hydrocarbons from oil refineries, various kinds of oils gas, etc., are used.

Boneblack and **ivory black** are obtained by heating bones with exclusion of air.

Graphite is becoming one of our most useful paint pigments, especially as a protection to iron and steel from rust.

Iron oxides give brownish colors varying to red, yellow, etc., depending upon the natural ores, as ochres, bole, pozzuole earth, sienna earth, etc. The ground ores are often adulterated with heavyspar, gypsum, clay, etc., for cheapness and shading of colors.

Red lead (red oxide or minium) is more highly oxidized than white lead or litharge and is obtained by properly heating the latter in a furnace or oven, in contact with the air, to a certain temperature (about 400° to 500° C.). It is used as a red pigment and is also a very durable cement for glass and for water pipes. Commercially, as a pigment, it is often adulterated with brick dust, red bole, heavyspar, oxide of iron, etc.—the last named being particularly objectionable.

Verdigris is a pigment usually mixed with white lead to produce a green paint. It is made by exposing thin copper plates to the air in contact with acetic acid.

Ochre is a clay containing oxide of iron, and when dried and ground is used as a pigment. It is usually of a yellowish color but by burning it gradually changes to red by the oxidation of the iron present.

Umber differs from ochre in containing a quantity of oxide of manganese in the clay in addition to the oxide of iron. The unburned or "raw" umber is dried and ground as a pigment for brown paint; while the calcined or "burnt" umber yields a reddish brown color.

Sienna is a ferruginous earth like ochre, the unburned of "raw" sienna producing a yellowish-brown pigment; if "burnt" (before being ground) it yields a reddish-brown pigment.

Asbestos is a fibrous hornblende (amphibole) or crysotile (serpentine) of various colors as white, gray, red, green and black. Its value in paint lies in its fireproofing qualities when applied to wood, or other inflammable material.

Vehicles—A vehicle in paint corresponds to lime paste in common mortar, forming the *binder* when dry. In calcimine, the pigment is zinc-white and the vehicle glue-sizing diluted with water; tinting is produced by adding the various coloring matters. For common paints linseed oil is universally referred as a vehicle, although any kind of varnish may be used.

Linseed oil is obtained from the seed of common flax, by (1) cold pressure, (2) hot pressure, (3) extraction. The first named process produces the food oil; the second and third, the article of commerce. The method of extraction is by the use of some solvent as benzine, naphtha, etc. Carbon disulphide yields fully 50% more oil than the cold-drawn process, but is objectionable when used with a lead pigment because the retained sulphur turns it dark. "Boiled" linseed oil is used as a vehicle for paints because drying is facilitated and it acts better with the pigment. Linseed oil is often adulterated with other oils as those of mustard seed, rape seed, hemp seed, cotton seed, etc. The engineer usually specifies "pure" raw or boiled linseed oil, the former being often preferred *alone* as a coating for steel when it leaves the shop.

Driers, such as compounds of lead, manganese and zinc, are simply oxidising agents for converting the oils from "vehicles" into "binders." Among the most common are litharge, red lead, lead acetate, oxides of manganese, borate of manganese, oxide of zinc, etc., or their various mixtures. These act as agents in conveying oxygen from the air to the oils, thus drying them.

Solvents.—A good solvent is slow to evaporate and flows sufficiently to efface the brush marks.

Turpentine is the best solvent. It is a repeated distillation of the resinous sap of certain coniferous trees, and dissolves readily the various substances used in paints. Only the pure turpentine should be accepted. It is composed entirely of carbon and hydrogen, but when exposed to the air it absorbs oxygen and turns yellow. It should be kept air-tight and away from the light. Turpentine has no substitute. Benzine, kerosene and some other oils are sometimes used either alone or as adulterants, but should be shunned.

House Paints.—White is obtained from white lead; black, from lampblack; red, from red lead (50) and red ochre (50); green, from verdigris (75) and white lead (25); chocolate, from spanish brown (96) and lampblack (4); stone color, from white lead (99) and burnt umber (1); lead color, from white lead (98) and lampblack (2).

The following table shows how various colors may be produced by a simple combination of two other colors. To produce "shades" of any color add black; to produce "tints" add white:

	Red.	Yellow.	Blue.	Orange.	Purple.	Green.
Red.....						
Yellow.....	Orange.					
Blue.....	Purple.	Green.				
Orange.....						
Purple... ..				Russet.		
Green.....				Olive.	Citrine	

Note.—Yellow and red produce orange; yellow and blue, green; purple and orange, russet; etc.

Special Paints.—These are made by mixing substances having special properties, with the pigments:

Aluminum paint is made from powdered aluminum and contains about 91% metallic aluminum, 6% aluminum oxide, 1½% silica, 1% water. Gas or air is forced under pressure into the molten metal which is vigorously stirred, and forms a powder in setting. This powder is crushed and run through sieves and polished. About 2 lbs. of the powder is mixed with one gallon of varnish composed of 1.5 galls. turpentine, ½ gall. palest copal varnish, 4 oz. palest terebine, 4 oz. carbonate of magnesia. The latter is allowed to settle and the clear varnish is drawn off.

Bronze paint is made by mixing filings of copper, brass, etc., with the pigment. It is used in painting iron and other materials.

Copper paint, mercury paint, arsenic paint and paris-green paint are poisonous to marine life and are used in painting ships bottoms. The copper paint is formed by mixing salts of copper with the pigment. The others are formed by mixing mercury, arsenic, and paris green, respectively, with the pigments used.

VARNISHES, LACQUERS, ETC.

Varnishes.—A varnish consists of a gum or resin dissolved in "spirit" or in oil, with perhaps some coloring matter added. The resinous substances are amber, animè, copal, mastic, resin, sandarac, shellac, for the lighter colors; and asphaltum and pitch for the dark colors. The solvents are "spirits," as ethyl alcohol, wood (methyl) alcohol, ether, benzol, chloroform, carbon disulphide, coal oils (light), turpentine; or "oils," as linseed, poppy, nut, hemp, castor, walnut, cotton-seed. The coloring matter is aloes, dragon's blood (a resin), tumeric, sanders-wood, saffron, anotto, indigo. The name of the varnish usually takes its name from the solvent, as *spirit varnishes* and *oil varnishes*.

Lacquering is the varnishing of polished metal surfaces, as brass. The lacquer is an alcoholic solution of shellac with some coloring matter added to give the desired tint. Being transparent or nearly so, the brass effect is visible while the metal is at the same time preserved from discoloring or oxidizing.

Japanning is varnishing with japan, a black varnish made with asphaltum (mostly) dissolved in turpentine.

GALVANIZING AND TINNING.

Galvanizing consists in dipping the iron or steel sheets, rods, bolts, wire, etc., in a bath of molten zinc. The coat is naturally very durable unless exposed to sulphurous smoke or other similarly destructive chemical agents.

Tinning consists in immersing the iron or steel sheets in molten tin and tallow. Tin plate, so called, is merely the thin metal sheet *coated* with tin. Terne plate is made by dipping the iron or steel sheets into a bath of tin and lead, being less expensive than tin plate and much inferior to it. It is used largely for roofing.

ELECTRO-PLATING.

This branch of Electro-Chemistry was evolved from discoveries made by Jacobi in 1838. By its use we are enabled to plate the cheaper and less durable metals with durable metal coatings. The agent employed is the electric current.

Electro-Chemistry is that branch of chemistry which treats of the chemical changes, produced by, or producing, electricity or electrical energy. It embraces the subjects of (1) Electrolysis, the decomposition of a chemical compound called an *electrolyte* into its constituent parts by an electric current; and (2) Electro-Metallurgy, the deposition of certain metals, as gold, silver, copper, etc., from their solutions by means of the slow action of an electric current. All electrolytes are either acids, bases or salts, and all electro-chemical reactions produce, or are produced by, these three classes of compounds. The transformation of chemical energy into electrical energy is through a system termed a voltaic or galvanic cell or battery, two or more *cells* in combination forming a *battery*.

Electrolysis—When an electrolytic substance is subjected to the action of an electric current it decomposes into *ions*, the *cations* (electropositive ions) seeking the "cathode" or negative pole, and the *anions* (electro-negative ions) seeking the "anode" or positive pole. Thus, when water is decomposed the hydrogen atoms (cations) are attracted to the negative pole, while the oxygen atoms (anions) collect at the positive pole.

Electro-Metallurgy is an electrolytic process by which the metal in an ore is separated from its impurities. It is one of the common processes, the others being: Smelting or heating of the ore; Amalgamation by the use of mercury; and Extraction by chemical solutions.

Electro-Plating embodies all the preceding principles. The article to be plated must first be cleaned thoroughly. It is dipped in a cleansing solution and then thoroughly rinsed with water so that none of the solution will remain. If necessary it is then placed in a scouring tray before going to the plating vat, where it is suspended in the plating solution from copper rods by means of short "slinging" wires of copper. The electric current used for depositing the metal from the plating solution may be obtained from any source which is convenient, either from a battery or dynamo. The following are some of the solutions used for electro-plating: For *gold* plating, a solution of gold cyanide and potassium cyanide; for *silver*, a solution of silver cyanide and potassium cyanide; for *copper*, an ammoniacal solution of copper and potassium cyanide; for *nickel*, the double sulphate of nickel and ammonia, or the double salt of nickel and ammonia; for *brass*, liquid ammonia and potassium cyanide added to a nitric acid solution of brass. Various other metals may be used for plating, as iron, tin, lead, platinum, bronze, etc.

Gold and silver may be deposited in excellent condition on a large number of the metals and alloys. Copper may be deposited on steel, iron, tinned iron, zinc; also on lead and tin, and their alloys; it is to be noted also that when any of these metals are to be gold-, silver-, or nickel-plated it is best to plate them with copper first, as copper plating adheres more firmly to them, and in turn is adhered to more firmly by the desired coatings. Nickel may be deposited on most of the common metals, including German silver, brass, and alloys of the soft metals.

PRESERVATION OF STEEL AND IRON.

Oiling, Painting, Asphalting, etc.—Many engineers specify that structural material on leaving the shop shall simply be coated with pure boiled linseed oil instead of being painted. This is doubtless good practice, as the oil penetrates the skin of the metal sufficiently to preserve it temporarily from rust and does not cover up any possible imperfections, which may be detected readily before erection. Among the best *paints* are the lead paints and the carbon paints. On ordinary structures they should last at least ten years if properly applied. Some of the best paint companies guarantee their paints for that period. Graphite paint and asphalt paint are also largely used. One gallon of paint will cover 600 sq. ft. and upward of metal, two coats; costing about $\frac{1}{8}$ to $\frac{1}{4}$ ct. per sq. ft.; or say, 2 to 3 cents per 100 lbs. of metal, for ordinary structures. For light bridges the cost per 100 lbs. would be greater; for heavy bridges and buildings, about 2 cents. This is exclusive of labor in painting.

Iron or steel thoroughly imbedded in cement or cement concrete is permanently protected from rust, but not from electrolysis.

For water pipes the following are used: Asphalt, coal tar (inferior), Smith's durable metal coating, Sabin process. The last named is a process of applying asphalt varnish, the pipe, after dipping, being baked for several hours at a temp. of 400° to 600°, thus producing an enamel coating.

Mill Scale on structural steel, can effectively be removed at the mill: (1) by "pickling" or cold rolling, at an expense of say 80 cents to \$2.00 per ton; (2) by the sand blast at a cost of about $\frac{1}{2}$ less; (3) by steel scrapers and wire brushes at considerably less expense if only ordinary cleaning is desired. Engineers differ as to the advisability of using the sand blast. The following opinions are expressed in Report of Committee E on Preservative Coatings for Iron and Steel, Proceedings A. S. T. M., Vol. VI: Mr. Phelps Johnson, Eng'r Dominion Br. Co., Limited, says: "In my experience I have found that an exposure to the weather for three or four months will ordinarily loosen nearly all the mill scale adhering to rolled material, and have considered that the subsequent removal by steel brushes of the slight coating of rust powder that is formed leaves the material in the best practicable shape for receiving the paint. I am of the opinion that the exposure to the weather may be prolonged to say 24 months without appreciable waste of metal or injurious pitting or roughening of the surfaces, and that there is but slight increase in the labor necessary to brush the surface clean for painting." Mr. Gustav Lindenthal, Consulting Engineer, says: "Mill scale is simply the magnetic iron oxide, which is insoluble in most acids, and an excellent preservative of the metal underneath, always provided that it adheres tightly to the surface of the metal. . . . I consider the use of the sand-blast for the cleaning of metal surfaces not only

useless, but detrimental. . . . The problem of painting iron and steel is not yet solved, in spite of the volumes of papers, discussions and reports on investigations which encumber the bookshelves." Mr. A. H. Sabin, Chemist, says: "For best work, the cleaning of structural steel work by the use of the sand blast is probably the simplest and most satisfactory way to have it done. The great objection to this, as to all such work, is the cost. . . . For ordinary work, the wire brush is an efficient means of getting rid of loose scale and dirt; but it is practically worthless for removing thick rust or anything which adheres closely. Much of such material may be removed by steel scrapers, but deeply corrugated spots should be cleaned out thoroughly with a chisel, and then well brushed."

Mr. George E. Thackray, Structural Engineer, Cambria Steel Co., says: "Sand blasting is almost useless and impracticable, as I have seen sand blasting done, exposing the metal surface, which was soon covered with a thick coat of rust before the painters could reach it, although both the sand blasters and painters were working with expedition."

Mr. Leonard M. Cox, Civil Eng'r. U. S. Navy, in describing the protective coating on the floating dry dock "Dewey," says: "The selection of a protective coating for the dock was made the subject of careful study. Samples of a number of the best known paints on the market, exclusive of the oxide paints, were applied to test-plates and subjected to different conditions. Three plates were coated with each sample, one was exposed to the weather at the company's works, a second was suspended half in air and half in water, and a third was submerged in the water of Chesapeake Bay. The tests extended over a period of 2 years, during the construction of the dock, and resulted in the choice of a mixture of red lead, white zinc and linseed oil in the following proportions: 100 lbs. of red lead, 15 lbs. of zinc ground in oil, and 5 galls. of linseed oil. It is only fair to state that in these tests a graphite paint manufactured in Detroit showed as good results as the red lead, but was not used because of the lack of available data bearing on its behavior in salt water.

"As the pontoons have more or less water in their bottoms at all times, except when self-docked, it was very necessary to provide adequate protection for their floors. Experiments with Bitumastic Enamel led to its application to the whole of the interior floors, and to all vertical bulkheads, braces, etc., to a height of 12 ins. The process of applying this mixture consists in a careful cleaning and drying of the metal, one coating of a solution, the function of which is to provide a surface to which the enamel will adhere, and a final heavy coating of enamel, from $\frac{1}{8}$ to $\frac{1}{4}$ in. in thickness, applied hot.

"Great care was taken to rid the hull plating of mill scale. The specification provided that all loose scale should be removed by hammering, scraping, and brushing with wire brushes, and to make its removal easier and surer, no paint was applied until a short time before launching. Nearly all the material, therefore, was exposed to the weather in the yard for periods ranging from 12 to 24 months. The existence of mill scale on the completed structure has such an important bearing on the subject of corrosion that the additional expense entailed by pickling would be a good investment in the way of insurance, and it is recommended that specifications for future docks include this requirement. It was also noticed that, in the process of weathering, the mill scale, where covered with paint, adhered closely and could not be removed without the use of the hammer and chisel. This scale, of course, will come off in time, and for this reason the requirement that all contact surfaces be given one coat of paint before assembling, should be limited, so as to apply to rolled shapes only."

PRESERVATION OF TIMBER.

Sources of Decay.—Decay may be due to (1) "wet rot," caused by the attack of certain large fungi which may enter the pores of standing timber or of timber used in damp places; (2) "fermentation," or decomposition of the cellulose tissues by the putrifying sap, which takes place in unseasoned timber; (3) "dry rot," which occurs in so-called seasoned timber, caused by the fungus *Merulius lachrymans* which can operate only in the presence of some moisture; (4) insect larvae and forest worms;

* Page 145, Vol. LVIII, Trans. A. S. C. E., in Paper No. 1042, entitled "The Naval Floating Dock—its advantages, design and construction."

(5) sea worms, as the teredo (*Teredo navalis*), limnoria and other marine wood borers which inhabit pure salt water and attack woodwork exposed to same. These sea worms were formerly confined to southern waters, but have gradually worked their way northward. (Not present in fresh water.)

Piling and timber grillage for submarine work need not be seasoned or treated with preservatives when below the action of the teredo, as timber will last thus for centuries. Piling in ordinary foundation work is practically preserved from contact with the atmosphere and the destructive elements, by being sealed in the surrounding moisture. It is customary to leave the bark on piles when driven in the water and to peel them when land driven. If exposed to teredo the piles are peeled and treated with some preservative. They may be copper sheathed, creosoted, tarred, kyanized, wrapped with tarred paper or other similar preparation secured by vertical strips of wood. Specially constructed piles are sometimes used, made up of strips of scantling, on the principle that teredo will not cross a seam between two strips; the composite pile thus made being sometimes treated also with a surface preservative. The process of encircling piles with tight casings, pumping out the water, and then applying steam, has proved to be expensive.

Creosoting consists in impregnating the wood with creosote oil (containing carbolic acid, cresylic acid, etc.) which is obtained from coal-tar distillations. The timber to be treated is placed in large iron cylinders, hermetically sealed and filled with steam at a low pressure, which softens and warms up the sap and woody fibres. The steam is then expelled and a partial vacuum produced (one-half atmosphere) with the air pumps, thus expunging the sap in the cells of the wood. The creosote oil is then turned into the cylinders and by means of hydraulic pressure is forced into the wood. There are many variations in the process. Creosoting is universally recognized as one of the best and most practical preservatives known. Timber should be framed before treatment as the surface saturation is strongest. Ordinary ties, 6x8—8, usually absorb about 25 pounds of creosote, costing from 40 to 60 cents apiece. Piling or timber exposed to the teredo require much more oil. The cost of creosoting piling may be assumed at 20 cents upward per lin. ft.; and timber \$16. upward per M. B. M. Creosoting probably ranks first, and burnettizing second, as a timber preservative, on a commercial scale.

One valuable point to be noted in creosoting is that the hard and expensive woods like oak and longleaf pine do not absorb the creosote oil as rapidly nor as thoroughly as do the softer and less expensive woods like beech; so that the soft woods, thoroughly impregnated, really outlast the harder ones.

For a good description of a creosoting plant see the article entitled "New Tie and Timber Preserving Plant of the A. T. & S. F. Ry, at Somerville, Texas," *Eng. News*, May 3, 1906.

Burnettizing is similar in method to creosoting. The solution used is chloride of zinc, a compound of zinc and hydrochloric acid. The results are inferior to creosoting, especially for bridge timbers. For ties, the comparison is not so marked. The cost of burnettizing is about $\frac{1}{2}$ to $\frac{1}{3}$ that of creosoting, but much depends upon the uses for which the timber is required. As water leaches out the zinc chloride in a comparatively short time when the treated timber is constantly submerged, it is evident that burnettizing will not do for piling. It even loses its strength in positions exposed to heavy rains.

Miscellaneous Notes.—Where timber is used in construction, the first proper guard against the actions of decay is the selection of the right kind of wood. Cedar, redwood, juniper, cypress, etc., are best able to resist ordinary decay, due to alternate wetness and dryness, hence their special usefulness for fencing, telegraph poles, ties, shingles, etc. Decay is something that enters the wood at some time or other, either during the period of growth or subsequently. There is little doubt that if a timber is cut from a perfectly healthy tree and its surface hermetically sealed so as to keep the interior in a constant state of either extreme moisture or dryness, it will last for thousands of years. The earliest and most primitive method of preserving wood was that of charring the surface, practiced before the dawn of history. Subsequently, it was discovered that piling kept constantly moist would last for centuries; and that the life of timber would

be prolonged greatly if kept dry from the influences of the weather, etc. Witness some of our old covered wooden bridges and the wooden joists of our colonial houses.

In the West where wooden bridges are common there are four principal methods employed to prolong the life of the structure: (1) Wooden covering (not common); (2) seasoning the timber to 12 or 15 per cent of moisture, and painting; (3) covering the upper surfaces of chords and end posts with galvanized iron (# 22 to # 27), allowing the sheets to lap a few inches down the sides; (4) treating the timber before erection, or painting it after erection, with a liquid preparation known as carbolineum avenarius. This preparation is also much used in preserving flooring and wooden paving blocks.

A coating of coal tar forms a good preservative on any material, wood, iron or stone, but its appearance is often objectionable. Note the use of tarred paper for roofing.

Copper sheeting for piles and ships' bottoms is very effective against the action of sea worms.

It is claimed that the life of wooden posts can be lengthened by boring an auger hole in the top, filling same with salt, and sealing with a wooden plug. Probably the more effective method is to bevel the tops of the posts, and plane and paint them. Posts of all kinds which set in the ground may be painted with tar for a short distance above and below the ground level, and an additional covering of metal may also be used. Telegraph poles are frequently treated in this manner, and their life greatly lengthened.

Chloride of zinc is often used for the preservation of timber, and as a disinfectant.

Creosote oil tends, if anything, to *preserve* railway spikes in ties; it also has a *deterrent* effect on the ravages of the teredo on piling.

Creosote and zinc chloride together forms Rutgen's process.

Barshall or Hesselmann process—zinc chloride and glue.

Kyanizing—corrosive sublimate.

SEASONING OF TIMBER.

The following is a digest of Bulletin No. 41, Bureau of Forestry, U. S. Department of Agriculture, issued in 1903, comprising an article entitled "Seasoning of Timber," by Hermann von Schrenk, in charge of Mississippi Valley Laboratory, Bureau of Plant Industry:

Distribution of Water in Timber.—(a) *Local Distribution.*—Water may occur in wood in three conditions: (1) It forms the greater part (over 90 per cent) of the protoplasmic contents of the living cells; (2) it saturates the walls of all cells; and (3) it entirely or at least partly fills the cavities of the lifeless cells, fibers, and vessels; in the sapwood of pine it occurs in all three forms; in the heartwood only in the second form, it merely saturates the walls. Of 100 pounds of water associated with 100 pounds of dry-wood substance taken from 200 pounds of fresh sapwood of white pine, about 35 pounds are needed to saturate the cell walls, less than 5 pounds are contained in living cells, and the remaining 60 pounds partly fill the cavities of the wood fibers. This latter forms the sap as ordinarily understood. It is water brought from the soil, containing small quantities of mineral salts, and in certain species (maple, birch, etc.), it also contains at certain times a small percentage of sugar and other organic matter. These organic substances are the dissolved reserve food, stored during winter in the pith rays, etc., of the wood and bark; generally but a mere trace of them is to be found. From this it appears that the solids contained in the sap, such as albumen, gum, sugar, etc., can not exercise the influence on the strength of the wood which is so commonly claimed for them.

The wood next to the bark contains the most water. In the species which do not form heartwood the decrease toward the pith is gradual, but where this is formed the change from a more moist to a drier condition is usually quite abrupt at the sapwood limit. In longleaf pine, the wood of the outer 1 inch of a disk may contain 50 per cent of water, that of the next, or second inch, only 35 per cent, and that of the heartwood only 20 per cent. In such a tree the amount of water in any one section varies with the amount of sapwood, and is therefore greater for the upper than the lower cuts, greater for the limbs than stems, and greatest of all in the roots.

Different trees, even of the same kind and from the same place, differ as to the amount of water they contain. A thrifty tree contains more water than a stunted one, and a young tree more than an old one, while the wood of all trees varies in its moisture relations with the season of the year.—Timber. By Filibert Roth (Bull. 10, Division of Forestry, U. S. Dept. of Agriculture, 1895.)

(b) *Seasonal Distribution*.—It is generally supposed that trees contain less water in winter than in summer. This is evidenced by the popular saying that "the sap is down in the winter." This is not always the case. Some trees contain as much water in winter as in summer, if not more. The average weight of lodgepole pine ties of the same size cut at Bozeman, Mont., in June, 1902, was 157 lbs.; in July, 144 lbs.; in Aug., 150 lbs.; in Sept., 157 lbs.; in Oct., 164 lbs. It is probable that this increase would keep up throughout the winter.

Relation of Water to Decay in Timber.—Low forms of plant life called fungi grow in wood, and by so doing disintegrate and dissolve portions of the wood fiber. As a result of this, the wood changes in its physical properties and is called decayed. When the fungus has extracted a sufficient amount of material, it forms, on the outside of the wood, fruiting bodies known as punks or toadstools, containing spores, which are blown about and infect sound wood. One of the most common of these wood-destroying fungi is called the *Lenitus lepidens*. The conditions necessary for the growth of these fungi are (1) water, (2) air, (3) organic food material, and (4) a certain amount of heat. The wood fiber and the organic substances found in the living cells of sapwood, such as albuminous substances, starch, sugar and oils, form the food supply necessary to start the growth of the fungus threads. A further requirement is oxygen; no growth will take place under water or in the ground at depths of 2 feet or more, the depth varying with the character of the soil. The best examples of this necessity for oxygen can be found in the way in which fence posts and telegraph and telephone poles decay at points just at or just below the surface of the ground, where there is a balance between the supply of air and of water.

For practical purposes water is the most important factor. Without water no fungus growth, and consequently no decay, is possible. "Dry rot," a form of decay in which the wood turns to a dry, brittle, charcoal-like substance, is commonly supposed to take place without any water. But such is not the case. The atmospheric moisture is sufficient to permit growth of the dry-rot fungus even if no moisture is contained in the wood. Too much water will prevent fungus growth, because it shuts off the air supply. The amount of water necessary for fungi growth is very small; and wood freshly cut contains more than enough, at all seasons of the year.

What Seasoning Is.—(a) *Difference Between Seasoned and Unseasoned Timber*.—Seasoning implies other changes besides the evaporation of water. Although we have as yet only a vague conception as to the exact nature of the difference between seasoned and unseasoned wood, it is very probable that one of these consists in changes in the albuminous substances in the wood fiber, and possibly also in the tannins, resins, and other incrusting substances. Whether the change in these substances is merely a drying out, or whether it consists in a partial decomposition, is as yet undetermined. Exposure to the wind and air, however, brings about changes in the wood which are of a nature that the wood becomes drier and more permeable. When seasoned by exposure to live steam, similar changes may take place. The water leaves the wood in the form of steam, while the organic compounds in the walls probably coagulate or disintegrate under the high temperature.

(b) *Manner of Evaporation of Water*.—The evaporation of water from timber takes place largely through the ends, i.e., in the direction of the longitudinal axis of the wood fibers. From the other surfaces it takes place very slowly out of doors, but with great rapidity in a kiln. The rate of evap. differs with the kind of timber and its shape. Thin boards and beams dry faster than thick ones; sapwood, faster than heartwood; and pine, faster than oak. Recent tests (not altogether conclusive) showed little difference in rate of evap. from sawed and hewn ties. Air-drying out of door takes from two months to a year, depending on kind of timber and climate. Wood which has been air-dried will absorb water in small quantities after a rain, or during damp weather, and lose most of it again

when a few warm, dry days follow. When soaked in water, seasoned timber absorbs it rapidly. It first enters the wood through the cell walls, and when these are soaked it will fill the cell lumen completely.

Seasoning and Preservative Treatment.—(a) *Seasoning and the Leaching of Salts.*—Where timber is chemically treated with salts dissolved in water, it is absolutely necessary to season it after the treating process, for two reasons: First, to prevent the rapid leaching out of the salts pressed into the wood; second, to prevent subsequent decay. In the case of ties, the leaching out takes place very rapidly when they are laid immediately after treatment.

(b) *Seasoning and the Processes of Preservation.*—The object of timber treatment is to get certain chemical compounds into the wood with as much thoroughness as possible. Because of its peculiar structure, wood will not allow of the penetration of liquids into its mass as does a sponge. The solution must work its way into the wood fibers through walls of wood substance. If a water solution is used for the impregnating material, it ought to fill every cell and permeate every wall, at least of the sapwood. The most successful method for timber treatment (excepting the boiling process) so far used consists in pressing the solution into the wood. If the wood cells and the walls are already full of water, it is evident that there will be great difficulty in making the water already in place give way to the solution. When the walls and cell cavities are free from water the process of absorption of a solution is facilitated. Besides this, prior seasoning not only brings about a reduction in the amount of water, but also results in a partial disintegration of the albuminous substances which offer more or less resistance to the entrance of solutions. The steaming of wood before treatment with solutions can never replace seasoning, as it can do no more than drive off part of the water, unless the temp. of the steam is sufficiently high to injure certain portions of the wood fiber itself.

Advantages of Seasoning.—The four principal advantages of seasoning timber may be enumerated as follows: (1) Seasoned timber lasts much longer than unseasoned; (2) Seasoning before chemical treatment greatly increases its effectiveness, and seasoning after treatment prevents the rapid leaching out of the salts introduced to preserve the timber; (3) The saving of freight due to a decrease in weight of 35 to 40% is sometimes a considerable item, even when compared with the total cost of the timber; (4) Seasoning allows the use of lower grade or softer timbers, so that red and swamp oak and beech are now being substituted for white oak, loblolly pine for longleaf pine, hemlock and tamarack for oak and pine, etc.; besides, the softer woods, being more porous, are more easily treated chemically.

To prevent checking and splitting of timbers while seasoning, many English roads use S irons, which are driven into the ends of timbers that begin to show such tendencies. Fig. 1 shows one of these irons of medium size, and Fig. 2 shows the method of applying same. The effect is a great saving.

Fig. 1.

Fig. 2.

How Timber is Seasoned.—(a) *Kiln Drying.*—The French Eastern Ry. maintains at Amague a plant for completing the drying of its ties after they have been seasoned in the open air, which consists of four kilns. The structures are about 50 ft. long by 46 ft. wide, and contain two pairs of hot-air galleries, each pair of which is provided with an independent furnace and can be operated as a separate kiln. The air enters, at first cold, from the outside into a lower chamber of the furnace, and becomes gradually

heated in its upward progress. It is at last discharged into a hot-air chamber which occupies all the upper part of the kiln. From this it is carried down to the galleries in which the ties are dried by four vertical pipes, having a cross section of 18 by 18 ins. Two pipes open into each gallery, at the end of which the trams bearing the ties pass out after the drying has been completed. Each tram carries about 40 ties slightly separated from each other, so that all the faces may be in direct contact with the hot air in the galleries of the dry rooms and with the tar oil in the cylinders. The four kilns in all contain 16 galleries, with a capacity of 5 trams each, in all 80 small trams. It is thus possible to dry about 3200 ties at once. With an annual output of 400,000 ties, seventy-two hours would be allowed for the average drying period. The temperature of the galleries is at the maximum of 30° to 35° C. at the entrance, and 70° to 80° C. at the delivery. As the trams are taken from the cylinders one at a time, the drying is progressive, and the wood, for this reason, is less liable to split or warp. To turn out 400,000 ties the furnaces of the four dry rooms consumed about 200 tons of fine coal and 250 tons of the trimmings, from saw machines, and wood trash and chips from the wood yard. This mixture develops a sufficient heat and offers the additional advantage of not wearing out the fire boxes by a two intense heat. The expense for fuel is about one-fifth of a cent for each tie.

(b) *Seasoning.*—Seasoning of timber has been carried on in a practical way for many years in Europe. Most of the European railroads season their ties for many months before they treat them. The Eastern French Railway piles its ties in open piles 11.4 ft. high, 8.8 ft. wide, and 8.8 to 65.6 ft. long. The ties are about 5 ft. apart. The ties are laid grillage fashion and spaced 4 ins. apart, except the two top tiers which are inclined (in the same direction) to shed water. At Amague, where kiln drying is subsequently used, oak ties are allowed to remain in piles for 15 to 20 months; and beech ties, 6 months. They are then kiln dried for from 60 to 80 hours at a temp. beginning at 35° and gradually brought to 75° C. Finally, they are treated with tar oil.

(c) *Seasoning by Steaming.*—Steaming is at best a makeshift and unless modified materially it can never replace open-air seasoning, supplemented possibly by kiln-drying. However, it ought to last longer than unsteamed, and where it is necessary to secure partially seasoned wood the steaming may do. The use of the vacuum pump does not materially improve matters, for it is not possible to maintain a sufficiently high temperature in a cylinder in which enough of a vacuum exists to insure the complete removal of all the water. [With the present state of our knowledge the injurious effect upon timber from high-temperature steam is not definitely known.]

(d) *Seasoning by Immersion in Water.*—It is very probable that immersion of timber for long periods in water materially hastens subsequent seasoning. The tannins, resins, albuminous materials, etc., which are deposited in the cells of the fibers of green wood, and which prevent rapid evaporation of the water, undergo changes when under water, probably due to the action of bacteria which can live without air, and in the course of time many of these substances are leached out of the wood. The cells thereby become more and more permeable to water, and when the wood is finally brought into the air the water escapes very rapidly and very evenly.

(e) *Seasoning by Boiling in Oil.*—It is sometimes claimed that all seasoning preparatory to treatment with a substance like tar oil might be done away with by putting the green wood into a cylinder with the oil and heating to 225° F., thus driving off the water in the form of steam, after which the tar oil would penetrate readily into the wood. This is the basis of the so-called "Curtiss process" of timber treatment. But the same objection made for steaming holds here, i.e., in order to get a temperature of 212° F. in the center of the treated wood the outside temperature would have to be raised so high that the strength of the wood might be injured seriously. A company on the Pacific coast which treats red fir piling asserts that it avoids this danger by leaving the green timber in the tar oil at a temp. which never exceeds 225° F. for from 5 to 12 hours, until there is no further evidence of water vapor coming out of the wood. The tar oil is then run out, and a vacuum is created for about an hour, after which the oil is run in again and is kept in the cylinders under 100 lbs. pressure for from 10 to 12 hours, until the required amount of absorption has been reached (about 12 lbs. per cu. ft.).

Conclusions and Recommendations.—Timber seasoning is a practical method for increasing the length of life of both untreated and treated timber. At the same time it forms the most important preliminary step to successful chemical treatment. The cost of seasoning is insignificant, while the returns amount to a considerable sum in the end. With the increased cost and scarcity of timber, every step leading toward a more economic use of our supply ought to receive attention. It is perhaps too soon to draw final conclusions, but the following general recommendations can confidently be made:

(1) Green timber should be piled in as open piles as possible as soon as it is cut, and so kept until it is dry. In the case of ties the 7 by 2 form of pile (tiers with 7 and 2 ties alternating) is the best. No timber should be treated chemically until it is dry.

(2) Timber treated with a preservative dissolved in water should be piled after treatment for several months at least to allow the water pressed into the wood with the salt to evaporate. Under no circumstances should timber freshly treated with a water solution be exposed to weathering influences.

CREOSOTE IN WELL-PRESERVED TIMBERS.

The following is a digest of Forest Service Circular 98, U. S. Dept. of Agriculture, issued May 9, 1907, comprising an article entitled "Quality and Character of Creosote in Well-Preserved Timbers," by Gellert Alleman, Prof. of Chem. in Swarthmore College:

"Of the various preservative processes for timber, those using coal-tar creosote are the most efficient, and, in the long run, are frequently the most economical as compared with the less expensive metallic-salts processes. Moreover, creosoted wood can be used for some purposes, as for salt-water piles, for which wood treated with metallic salts is but slightly more durable than untreated timber. Recent reports on the service of creosoted railroad ties, and of salt-water piles, have shown that, while proper treatment gives excellent results, much of this timber was not treated properly and has not lasted as it should. It is imperative that we should know, as completely as possible, just what constitutes efficient creosote treatment. This depends on three things—the amount of creosote, its character, and the thoroughness with which it penetrates the timber. The proper amount of creosote will depend upon the intended use of the timber. For instance, piles which must resist the attacks of marine borers need more creosote than telephone poles, and those in warm waters require more than those in cooler waters.

"The sort of creosote best suited to prevent decay and the inroads of marine borers can be ascertained only by many careful experiments. The best means for securing a maximum penetration of the oil is a problem complicated by many factors such as wood structure, moisture, etc. One way of approaching this problem involves a study of the nature of the creosotes present in timbers which have given long service. The results of a series of analyses of the oils present in such timbers forms the most important part of this paper. A brief account of the source and composition of coal-tar creosote precedes the description and discussion of the experiments.

Manufacture and Composition of Creosote.—(a) *Source and Composition of Coal Tar.*—When certain varieties of coal are heated in an oven or retort, in the absence of sufficient air for their combustion, the coal is decomposed and gas, tar, and coke are formed. The gas and tar rise from the heated mass and the coke remains in the retort. Coke and illuminating gas are manufactured in this way. Where coke is the main product desired the "beehive" oven is used and the gas and tar are not collected, but when the volatile materials are to be collected the "by-product" oven is used. In making illuminating gas the coke and tar are regarded as by-products, and one of the problems of management is how to dispose of these by-products to advantage.

Coal tar is an extremely complex mixture of organic compounds, varying with different coals and with different treatments of the same coal, which will yield at the same plant various qualities of coke, gas and tar, depending on the amount of heat applied, the quantity of air admitted, and the season of the year. With a low heat a relatively small amount of gas and tar is evolved and the tar contains large quantities of compounds of the paraffin series; but with a high temp. much larger amounts of gas

and tar are obtained and the predominant compounds of the tar, in nearly all cases, are those of the aromatic series, as benzene, toluene, phenol, naphthalin, anthracene, etc.

(b) *Production of Creosote from Coal Tar.*—The first distillation of crude tar, in which several separate fractions are usually taken, is made in large iron retorts holding from 10 to 30 tons. The forms of the retorts and the manner of controlling the distillation vary more or less in different work. In some cases the still is provided with a thermometer enclosed in an iron tube screwed into the still head; in other cases the time for changing the receiver for various fractions is judged solely by the specific gravity and other properties of the distillates.

In Germany the fractions are frequently taken as follows: The temp. is that registered by the thermometer in the tar at the beginning of the distillation, but free from the oil and indicating the temp. of the vapor passing over when anthracene oil begins to distil: First light running up to 110° C.; light oils, 110° to 210° C.; carbolic oils, 210° to 240° C.; heavy or creosote oils, 240° to 270° C.; anthracene oils, 270° to 400° C.

At many English works the following fractions are taken with the thermometer placed as in the German procedure just cited: Light naphtha up to 110° C.; light oil, 110° to 170° C.; carbolic oils, 170° to 225° C.; creosote oils, 225° to 270° C.; anthracene oils, 270° to 360° C.

These temperatures are by no means universally accepted in the respective countries, and one or more fractions are often omitted; when, for example, it does not pay to extract carbolic acid, or when the demand for anthracene is limited.

Owing to the variable constitution of the tar and to the different temperatures between which fractions are taken, the products of this preliminary separation are frequently widely different in physical character and chemical composition. In distilling according to the German method given above, the "first runnings" and "light oils" contain, among other things, benzene, toluene, and the xylenes; the "carbolic oils" contain phenol, the creosotes, and some naphthalin; the "creosote oils," small quantities of phenols, naphthalin, anthracene, and many other hydrocarbons; the "anthracene oils," anthracene, acridene, etc. The residue in the still is either soft or hard pitch, according to the point at which the distillation is stopped. When the anthracene oil is completely distilled, the residue is largely hard pitch or carbon, and this is used as a briquette binder and in the manufacture of electric light carbons. When the distillation is stopped at an earlier stage, soft pitch is obtained which contains a considerable quantity of the high-boiling tar constituents; and is used for roofing and for builders' paper. At present there is almost no market in America for hard pitch, whereas the demand for soft pitch for roofing is very great, which explains why the distillation of tars is not carried so far here as in some foreign works.

(c) *Statistics of Production and Importation of Creosote.*—The following table gives, approximately, the amount of Coal Tar produced in the U. S., also the amount of Creosote Oil produced and imported, in millions of gallons, for the years named:

Year.	Coal Tar.				Creosote Oil.				Remarks.
	From Gas Works.	From By-Product Ovens.	Total. Millions of Gals.	Price per Gallon.	Produced in U.S.	Imported.	Total. Millions of Gals.	Price. per Gallon.	
1898	24.38	4.02	28.40	3.7cts.					Present price of oil much higher.
1903	40.80	22.15	62.95	3.49 "	4.00	3.71	7.71	5.8cts.	
1904	41.73	27.77	69.50	3.04 "	4.85	3.78	8.63	6.3 "	
1905	43.64	36.38	80.02	2.73 "	5.80	7.75	13.55	5.4 "	

The estimate for 1903 includes the tar produced at 1956 "by-product" ovens, assuming 8.5 gallons of tar per ton of coal coked. It is generally stated that 12.5 gallons per ton of coal may be obtained from gas works, that the general average from gas works and from ovens is a little over allons. Moreover, it is usually assumed that the average coal tar produced in this country contains at least 10% of oils which can be used as added to, creosote oil.

d) Composition of Commercial Creosote.—Technically speaking, the fraction of oil passing over between 240° and 270° C. during the first distillation of the crude coal tar is known as "creosote oil," "heavy oil," or "oil of coal tar." In practice, however, the oily residues which remain after extracting carbolic acid, naphthalin, and anthracene from various distillates in which they occur are added to the creosote oil, in consequence, many of the creosote oils of commerce contain considerable amounts of materials having boiling points higher than 270° C., lower than 240° C. As a matter of fact, it is the practice at nearly all stilling plants to add to the "creosote well" or tank all those oils and residues which cannot profitably be worked over and used to greater commercial advantage. The solvents which are used in the purification of naphthalin and of anthracene are sometimes added to the "creosote well," this accounts for the occasional presence of paraffin oil in creosote.

The "creosote well" or tank is usually constructed of steel plates, and is fitted with inclosed steam coils at the bottom, in order that the solid materials crystallizing out can be melted before the oil is delivered to tank or tank steamers, or barrels. A stirring device is also frequently used to secure uniformity in quality of supply.

The creosote oil of commerce contains phenol (carbolic acid), the ortho, meta, and para cresols, naphthalin, the α and β methyl-naphthalins (the former being a liquid, the latter a solid melting at 33° C.), anthracene, anthracene, arcidene, and small quantities of certain high-boiling compounds and acids. When first distilled, creosote has a distinctly fluorescent appearance, and is light green in color. There is strong evidence for the belief that some of the individual constituents in creosote oil combine with oxygen and probably form new products.

At certain works, carbolic acid is extracted and the creosote oil coming from such places is low in "tar acids;" at other places, naphthalin is of considerable commercial importance and the creosote oils obtained from such works contain little naphthalin. Usually anthracene separates from the creosote oil, and in the event that the latter is frozen out, the former is lacking in the oil which is placed on the market. In America the creosote oils usually contain large amounts of naphthalin, very small amounts (about 5%) of phenols or cresols, and practically no anthracene (the reason previously mentioned). It is evident that these variations in manufacture result in creosotes differing greatly in physical and chemical properties; some are rather thin oils, some are almost entirely solid with naphthalin, and some are heavy oils with a large proportion of high-boiling constituents.

The different sorts of oils are believed to have different preservative qualities when injected into timber, but there is, unfortunately, a lack of uniformity of opinion. Some investigators have advocated oils rich in naphthalin, some those containing much naphthalin, some those containing a maximum of the high-boiling compounds. But little has been published on the subject.

Analyses of the Creosote Extracted from Timber Well Preserved after Service.—To determine what is, in fact, a good oil, a natural way is to examine the composition of those oils which have protected treated timber satisfactorily. This can be done by extracting and analyzing the oil from timbers the exact history of whose service is known. The writer (Professor Alleman) secured from various sources a number of creosoted timbers which had been in varied and extended use under markedly different conditions. The oils from these timbers were extracted and analyzed with the following results:

Results of the Analyses.—The results of the analyses of the creosote extracted from 37 different samples of wood are given in Table 1, following. The majority of these samples were obtained from various English companies using creosoted wood. Such details as could be learned concerning the history of the timbers are given in the footnotes.

a Twenty years as a tie and thirteen years as a fence post.

c Under rail.

d Paving block No. 54.

e Paving block No. 55.

GLASGOW AND SOUTHWESTERN RAILWAY, SCOTLAND:

Tie No. 106 taken out of the Main Line February 12, 1905, near Milliken Park; put in during 1889. Creosoted with 2½ gallons of gas-works creosote of 1.010 specific gravity at 60° F.

Tie No. 104 taken out of the Main Line February 6, 1905, near Elderslie Station; put in during 1887. Creosoted with about 2½ gallons of oil to the tie.

Tie No. 113 taken from the Main Line April 16, 1905, near Elderslie Station; put in during 1887. Creosoted that same year with about 2½ gallons of oil to the tie.

Tie No. 109, same history as No. 106.

GREAT WESTERN RAILWAY, HEATH DIVISION, ENGLAND:

Pile No. 118 was in salt water at New Milford 47 years; not decayed, but attacked by Linnoria.

Tie No. 107 was in sidings at Eastern Depot, Swansea, for 42 years.

Tie No. 105 served for 20 years in the Main Line at Hirwain (Vale of Neath), and afterwards was used as a fence post for 13 years.

Memel pile No. 1 was in a tidal river at Loughor for 53 years. Treated with crude coal tar and not analyzed.

Memel pile No. 2 was in salt water at Llanelly Docks for 58 years. Treated with crude coal tar and not analyzed.

LONDON AND NORTHWESTERN RAILWAY COMPANY, ENGLAND:

Ties No. 103 and No. 110 installed in the road for permanent way purposes in 1886; removed February, 11, 1905. They were creosoted with blast furnace Scotch oil in 1886.

NORTHEASTERN RAILWAY COMPANY, ENGLAND:

Paving blocks Nos. 88 and 89 removed in perfect condition after being in use at Hull for 20½ years.

Tie No. 114 was under water for 20 years, and afterwards used as a tie under piles of timber in the dockyard for 10 years, a total service of 30 years.

CITY ENGINEER, HULL CORPORATION, HULL, ENGLAND:

Paving blocks Nos. 90 and 91 laid with close joints in 1894; removed in February, 1905, in perfect condition. Paving block No. 92 consisted of three broken blocks laid with open joints in 1892; not decayed when removed in 1905. Treated with creosote and pitch on the outside; not analysed.

MARYPORT AND CARLISLE RAILWAY COMPANY, ENGLAND:

Ties Nos. 108 and 137 creosoted in 1881, placed in track 1882, and removed in 1905. Tie No. 137 was not analyzed.

HIGHLAND RAILWAY COMPANY, SCOTLAND:

Ties Nos. 2, 3, and 41 were in service in a gravel ballast, damp bed, for 20 years, 20 years, and 22 years, respectively. These ties were seasoned two years before treatment and stacked six months after creosoting before being placed in the track.

NORTH BRITISH RAILWAY COMPANY, SCOTLAND:

Tie No. 101 was in the track 21 years; No. 102, 21 years; No. 112, 14 years; No. 100, 14 years (not analyzed). These ties were taken out at different parts of the system.

CLYDE NAVIGATION TRUST, GLASGOW:

Pile No. 116 is from the part of the pile which was above high-water level, and was therefore exposed to the air.

Pile No. 111 is from the part of the pile between high and low water. It was therefore exposed to the wash of the water.

Pile No. 117 is from the part of the pile which was always under water.

Pile No. 4 is from the part which was buried in the ground.

Pile No. 5 is from the part of a pile above high water; creosoted with 8 pounds per cubic foot.

Tie No. 8 was laid in slag in the year 1883.

Tie No. 9 is a part of a Baltic redwood tie laid in 1889. It was bedded in concrete and causewayed over with granite sets. Both of these ties were creosoted with 2½ gallons of gas creosote of not less than 1.010 specific gravity at 61° F.

Pile No. 115 is from a part of pile No. 5 between high and low water; not analyzed; creosoted with 8 pounds per cubic foot.

NORFOLK CREOSOTING COMPANY, NORFOLK, VA.:

Pile No. 81, section of a creosoted pile put in Santiago Harbor Cuba, April, 1887; taken out in perfect condition November, 1902.

Pile No. 82, section of a creosoted pile put in Tampico Bay in May, 1891; taken out in perfect condition October, 1902.

Pile No. 83, section of a pile treated with creosote and resin; removed after seven years badly attacked by Teredo.

Pile No. 84, section of a creosoted pile put in a drydock at Newport News, Va., May, 1881; removed in good condition October, 1901.

Pile No. 85, section of a creosoted pile in service for 17 years at Newport News, Va.

Tie No. 86 was in the track for 22 years at Houston, Texas.

INTERNATIONAL CREOSOTING AND CONSTRUCTION COMPANY, GALVESTON, TEX.:

Piles Nos. 50 and 51 were in Galveston Bay for 29 years.

Paving block No. 52 was in service in the street at New Orleans, La., for 34 years.

Paving block No. 53 was in service in Galveston for 29 years.

Paving blocks Nos. 54 and 55 were in use at Galveston for 9 years. They showed poor service.

BELL TELEPHONE COMPANY:

Conduit pipe No. 67 was in service as conduit at Philadelphia, Pa., for 14 years; removed in perfect condition to make extensions of service.

In the following Table (2) the 37 samples described above are grouped in classes and the average results of all the well preserved timbers are given for each class:

2.—ANALYSES OF EXTRACTED OILS.

Samples.	Average service.	Creosote to the cubic foot.	Distillation of extracted oil.								
			To 205° C.	205° to 245° C.	245° to 270° C.	270° to 320° C.	320° to 420° C.	Residue above 420° C.	Solid naphthalin from distillates.	Solid anthracene oil from distillates.	Tar acids.

Discussion of the Analytical Results.—(a) *Quantity of Oil Found.*—The average figures show that the quantity of creosote in these long-service timbers was not excessive. Practically nothing is known of the amount of oil which was injected into the various samples. Six of the ties, Nos. 8, 9, 104, 106, 109, and 113, were said to have received 2½ (English) gallons of creosote each or 10.50 lbs. of oil per cu. ft., assuming the spec. grav. of the oil at 1.05 and the volume of each tie at 2½ cu. ft. The average amount present was 8.56 lbs. The American piles (all set in warm water, those farthest north being on the Virginia coast) show a much higher content of oil than the English samples. For the paving blocks, there is a considerable contrast between the quantity of oil present in those which gave good service, and the sample which was short lived. The difference in

service was doubtless due to two factors, the quantity and the quality of the injected creosote; it is impossible to say which had the greater influence.

In general, the results tend to show that 10 lbs. of creosote per cubic foot is ample for railroad ties, and that piles require from 10 to 20 lbs., according to the location in which they are to be placed. If a creosote contains much light oil, a proportionately larger quantity must be used.

(b) *Character of the Extracted Creosote.*—A difficulty in the proper interpretation of the results of the analyses arises from our ignorance of the quality of the oil used in treating the various timbers. It is, therefore, possible to believe that the materials which have volatilized from the timbers have created an antiseptic environment which has been a most important factor in preserving the wood. Aside from this, however, the analyses furnish a strong argument in favor of the use of heavy oils. For example, tie No. 6 had seen but 14 years' service, two-thirds the average of the ties, and doubtless would not have suffered decay for many years to come, yet it does not contain more light oil than the average of the tie group, but, on the contrary, the creosote from this specimen was over half recovered as solid anthracene oil. If the constituents present in the timbers represented a non-efficient residue from which the effective light oils had evaporated, we should expect to find a relatively high proportion of light oils in this tie which had seen a shorter term of service. The natural interpretation of the results is that it is the heavy, high-boiling compounds which stay in timber and are an efficient barrier to the entrance of water and to the attacks of fungi and borers.

The creosotes recovered contained practically nothing which boiled below 205° C. The general average shows that 32.9% of the oils distilled below 270° C., and 66.95% above—that is, two-thirds above and one-third below this rather high temperature. Another noticeable fact is the large amount of solid anthracene oil recovered from the distillates of many samples, the highest being 57%.

A distinctive feature of the creosotes from American piles was the quantity of naphthalin which they contained. The average from this class of timbers was nearly 26%, and one sample showed over 48%. It appears probable that the creosotes used in treating these timbers contained much more naphthalin than the oils applied to the English piles. The results indicate that this substance possesses value for timber treatment, although it probably is inferior to anthracene oil. It is worth noting that these long-lived American piles contained more anthracene oil than naphthalin.

Perhaps the most striking thing is the disappearance of the tar acids. It is certainly conservative to place the original tar-acid content at 5%. Yet the extracted oils showed but one tenth of this amount. It is possible that the compounds, on account of their hydroxyl groups, have undergone chemical changes during the many years that they have been exposed to varying amounts of water and air, to the reactive lignin portion of the wood, and to the numerous compounds present in creosote. On the other hand, these phenol bodies have been volatilized or been washed from the timbers.

It appears, therefore, that light oils, boiling below 205° C., will not remain in timber, but that heavy oils, containing a high percentage of anthracene oil, will remain almost indefinitely and protect the wood from decay and boring animals. It is probable that naphthalin stays in wood for many years, but whether it is as valuable as anthracene oil is an open question. The value of the tar acids has apparently been overestimated by many persons, for although it has not been proved that they are valueless, they have been shown to possess poor staying qualities.

EXCERPTS AND REFERENCES.

The Protection of Ferric Structures from Corrosion (By M. P. Wood. Trans. A. S. M. E., 1901; Eng. News, Sept. 16, 1901.)—(1) **Iron Oxide Pigments.**—To neutralize the sulphur element natural to the ore or developed in roasting, it is the common practice to add carbonate of lime (common chalk) to the amount of 5 to 10% by weight of the iron oxide. (2) **Boiled Oil vs. Pigment Coatings.**—Many engineers have abandoned the use of iron oxide and other uncertain patent paint compounds, but still adhere to the use of oil for the first coating. The writer believes that a good pigment paint is much better than oil coating. **Asphaltum Coatings.**—The so-called asphaltum paints in general have thus far proved to be quite as ineffective protective coatings as any of the iron oxide or miscellaneous

compound paints. **Linseed Oil.**—Discusses the processes of extracting the oil, etc. **Painting at the Mill.**—Does not advocate painting the iron or steel just after it has left the rolls or hammer, and while hot; but just before assembling.

The Painting and Sand-Blast Cleaning of Steel Bridges and Viaducts (By Geo. W. Lilly. Engrs. Club, Columbus, O., Feb. 1, 1902; Eng. News, April 24, 1902).—Raw Linseed Oil is said to make a better binder than boiled linseed oil, but it sets so slowly that in certain locations, such as viaducts subject to the blast, smoke and steam from locomotives, its use is inadvisable, because it will be filled with cinders and otherwise seriously injured before it is dry. The Pigments most commonly used for anti-rust paints on steel may be classed under the names red lead, iron oxide, carbon and graphite. Each of these has had its champion among men who have had considerable experience in the use of paints, while the experience of many experts has led to the conclusion that "red lead, oxide of iron, carbon and graphite all give results which average about the same." **Mixing and Applying the paint.**—All paints should be thoroughly mixed by machinery and subsequent grinding with a burr-stone mill if possible. But red lead, which is inclined to settle and harden somewhat in the mixture and make it difficult to spread and also diminish the coherence of the coating made by it, can be quite thoroughly mixed by hand when the facilities for machine mixing are not at hand; and this is advisable in most cases, for the reason that it is usually impossible to have it mixed at the time it is needed except it be done by hand. All painting should be done, if possible, when the temperature of the atmosphere is above 55° F., when little trouble will be experienced in spreading red lead or any other of the commonly used paints. If painting is done when the temperature is lower than this, the paint should be warmed up by placing it in a vessel, which is set in water heated to a temperature of 130° to 150° F., and each painter should be frequently supplied with warm paint when the paint in his bucket becomes cool. **Cleaning the Steel Before Painting.**—Before any paint or other coating of any kind is permitted to be applied to the iron or steel of a bridge or viaduct, all the scale, rust, dirt, grease and other foreign substances, as well as dead paint, should be removed from its surface, so that the coating may come into intimate contact with the clean surface of metal, and thus give the best condition for firm adhesion of the coating to the metal. The sand-blast has been given sufficient trial to make it reasonable to say that such cleaning as is necessary on new work at the shops—that is, removal of mill scale and some rust and grease—can be done at about $\frac{1}{4}$ ct. per sq. ft. of steel surface cleaned, and possibly a little less. On this basis the cost per ton for cleaning steel plates would be: For plates 1" thick, 49 cts.; $\frac{3}{4}$ " thick, 98 cts.; $\frac{1}{2}$ " thick, \$1.96. For shapes: 7" I-beams, weighing 17.6 lbs. per ft., \$1.35 per ton; 12" I-beams at 50 lbs. per ft., 80 cts.; the heavier sections costing less and the lighter sections costing more per ton. The average cost for cleaning most plate girder bridges would probably be about \$1 per ton; and the cost for a truss bridge might vary from \$1 per ton for heavy bridges to \$1.75 per ton for light bridges. This article contains an illustrated description of the Newhouse sand-blast machine used in cleaning viaducts at Columbus, O.

Creosoting Wooden Poles for Electric Line Work (By W. E. Moore. Read before Nat'l Elec. Lt. Ass'n, at Cincinnati, O., May 20, 1902; Eng. News, May 29, 1902).—Iron Poles or creosote poles are as yet seldom used by lighting companies, though iron poles are extensively used for street railway purposes. **Wooden Poles.**—Wooden poles are usually of cedar, heart-sawed pine, cypress, juniper or redwood, and are generally used on account of low cost and the comparative safety with which workmen may handle the live wires when standing on the cross-arms, as wood is a fair insulator. Red-cedar and white-cedar poles, while they have a comparatively long life, have now become so scarce that it is extremely difficult to secure them in sufficient numbers of suitable sizes for electric light lines at any price in the Eastern or Southern market, though there is yet a considerable supply of white cedar in the Northwest. Heart-sawed pine poles have a somewhat longer life than cypress, ranging from 8 to 9 years; but sap pine, though readily secured in sticks of suitable size and necessary length, is never used, on account of its rapid decay. **Study of Preservation of Poles.**—The Augusta Ry. and Elec. Co. began about 9 years ago to study the problem of treating poles. The first experiment consisted in charring

the butts of the poles, up to about 1 ft. above the earth line, and then saturating them with a coal-tar paint; but this was found to be of little service. Painting the poles with various brands of preservative compounds sold under various trade names was then tried, but with little or no beneficial results. In the meantime the poles then in use, almost entirely of cypress, continued to rot out after an average life of about 5 or 6 years. **Creosoting Plant.**—Consists of a steel cylinder 6' dia. and 102' long, with heavy cast-iron heads, securely supported on hinges and arranged to be clamped against a fibrous gasket on the head of a cylinder so as to resist a hydrostatic pressure of 150 lbs. There is a narrow gage railway through it, with tracks continuing beyond ends of cylinder, which has a series of 1" pipes laid from end to end and covering the bottom, and supplied with steam from an 80 H. P. return tubular boiler, the steam being superheated to a temperature of 400° to 500°. To the cylinder is also connected a direct-acting vacuum pump, 14" x 24", and, again, a direct-acting oil-pressure pump, 10" x 18". **Method of Treatment.**—Is fully described. **Cost of Treatment.**—Cost of average size (say 34 ft. long, 8" dia. at top) cypress pole, from \$1.75 to \$2 each; and cost of creosoting, about \$20 per M. B. M., or about twice the first cost of pole. Assumed that life of treated pole will be prolonged 4 to 6 times that of untreated. **Effect of Creosoting, on Linemen.**—Disagreeable in handling; dangerous to linemen when handling wires carrying 1000 to 3000 volts, as the creosoting lowers the electric resistivity of the timber.

Creosoting Works of the Western Ry. of France (By J. M. Merklen. May number of "Revue Generale des Chemins de Fer;" Eng. News, July 27, 1905).—Full description of Plant, Method of Treatment, and illustrated Method of Piling Ties for Seasoning.

Tie and Timber Preserving Plant of the A. T. & S. F. Ry. at Somerville, Texas (Eng. News, May 3, 1906).—Description of Creosoting Process, Seasoning, Inspection and Marking, Creosoting Plant, Experimental Plant, Tanks, Gages and Pipe System, etc. Illustrated.

The Inspection of Treatment for the Protection of Timber by the Injection of Creosote Oil (By H. R. Stanford. Trans. A. S. C. E., Vol. LVI).

Coal Tar Paints (Eng. News, Aug. 16, 1906).—Discussions and references to other articles.

Corrosion of Steel in Reinforced Cinder Concrete (By W. H. Fox. Eng. News, May 23, 1907).—Following conclusions from results of experiments: In no case was any evidence found underneath the collars of neat cement which surrounded a portion of each steel specimen. To secure a dense homogeneous cinder concrete, a thorough tamping is necessary. A rich mixture, either a 1:1:3 or one in which the proportion of cement to aggregate is larger, should be used in all cases. The greatest care should be taken in mixing the materials, and it may be necessary to resort to the seemingly impractical method of coating the reinforcement with grout before placing in the concrete.

Cleaning Steelwork by Sand-Blast and Painting by Compressed Air (By De Witt C. Webb. Eng. News, Sept. 19, 1907).—**Plant.**—Following outfit, purchased at cost of \$2090, delivered at U. S. Naval Station, Key West, Fla.: 1 hor. gasoline engine, 20 H. P.; 1 air compressor, capac. 90 ft. of free air per min. compressed to pres. of 30 lbs. per sq. in. in one stage, belt connected to engine; 1 rotary circulating pump, belt connec. to engine; 1 galv. steel water tank; 1 air receiver, 18" x 54"; (above all mounted on steel framed wagon with wooden housing.) 2 sand-blast machines, at capac. of 2 cu. ft. of sand each; 2 paint spraying machines, one a hand machine of 1-gal. capacity for one operator, the other of 10-gal. capac. for two operators; 100 lin. ft. of sand-blast hose; 200 lin. ft. of pneumatic hose for sand-blast machines; 400 lin. ft. of pneu. hose for painting machines; 4 khaki helmets, with mica-covered openings for the eyes; 200 lin. ft. of 2" galv. pipe. **Cost of Cleaning.**—2000 sq. ft. of previously untouched surface was thoroughly cleaned and 7000 sq. ft. of hand cleaning was all gone over and much improved at a total cost for labor of \$97.68, and for gasoline (at 19 cts. per gal.) of \$16.15. **Cost of Painting.**—The coal-tar

paint originated by A. C. Cunningham was used (see Eng. News, July 12, 1906), prepared with the following proportions (by volume): coal tar (4 parts), kerosene oil (1), Portland cement (1); cost, 15 cts. per gallon. Shed "A" required 64½ gals. for 9000 sq. ft. or 1 gal. to 140 sq. ft., at cost for labor of \$28.16, and for gasoline of \$3.80. Shed "B" required 86 gals. for 12500 sq. ft. or 1 gal. to 145 sq. ft., at cost for labor (including cleaning, painting, moving, setting up and removing) of \$460, and for gasoline, \$81.

Paints for Concrete (By G. D. White. Proc. A. S. T. M., Vol. IX, 1900).—With discussions.

Comparison of Various Processes of Preserving Timber (By G. B. Shipley, Eng. News, Oct. 14, 1902).—*Approximate cost of treating ties, excluding royalty*:—Burnetizing process: about ¼-lb. dry zinc per cu. ft., \$0.12 per tie. Wellhouse process: about ¼-lb. zinc per cu. ft. plus glue and tannin, \$0.16 per tie. Card process: about 1½-lbs. creosote and ¼-lb. dry zinc per cu. ft., \$0.18 per tie. Rueping process: about 6-lbs. creosote per cu. ft., \$0.225 per tie. Lowry process: about 6-lbs. creosote per cu. ft., \$0.225 per tie. Absorption process: about 6-lbs. creosote per cu. ft., \$0.23 per tie. Full cell process: about 10-lbs. creosote per cu. ft., \$0.335 per tie. The above costs are based on creosote oil at \$0.07 per gal. and dry zinc chloride at \$0.04 per lb. It costs about ¼-cent per tie to handle in the yard. *Timber*.—The cost of creosoting timber with 10 lbs. of creosote per cu. ft. will be about \$8 per 1000 ft. B. M., and for each additional pound of creosote used add about \$0.75 per 1000 ft. B. M. based on creosote oil at \$0.07 per gal. Burnetizing, ¼-lb. dry zinc chloride per cu. ft., \$4 per M. B. M.

20.—LUMBER AND LUMBERING.

Stumpage.—The following is a digest of Forest Service Circular 97, U. S. Dept. of Agriculture, issued April 24, 1907, and entitled "The Timber Supply of the United States," by R. S. Kellogg, Forest Inspector:

The percentage of the total lumber cut furnished by the principal regions since 1860, according to census figures, is as follows:

1.—GEOGRAPHICAL DISTRIBUTION OF TOTAL LUMBER PRODUCT.

Year.	North-eastern States.	Lake States.	Southern States.	Pacific States.
	<i>Per cent.</i>	<i>Per cent.</i>	<i>Per cent.</i>	<i>Per cent.</i>
1850.....	54.5	6.4	13.8	3.9
1860.....	36.2	13.6	16.5	6.2
1870.....	36.8	24.4	9.4	3.8
1880.....	24.8	33.4	11.9	3.5
1890.....	18.4	36.3	15.9	7.3
1900.....	16.0	27.4	25.2	9.6

The principal estimates of the stumpage of the U. S. made since 1880 are given in Table 2. The first, by Sargent (1880), in addition to being too low for almost every species considered, with the possible exception of the hardwoods, is notable for its omission of Douglas spruce—which exists today in greater quantity than any other of our valuable timbers—and yellow pine, another important species. The next estimate, that of Hotchkiss (1898), does not go into details. The next estimate, by Gannett (1900), was most carefully prepared. That by Fernow (1902) is a regional estimate. Long's estimate (1903) does not cover cypress, sugar pine, or hardwoods. Its principal point of interest is that it differs so radically—about 38%—from that of the census of 1903 upon the stumpage of yellow pine. The last estimate given in the table is that published in the "American Lumberman," Sept. 23, 1905. It is based primarily upon census data, with the addition of some species and with increased figures for others:

2.—ESTIMATES OF STUMPAGE OF THE UNITED STATES.

Kind of Timber.	Census, 1880.	Hotchkiss, 1898.	Census, 1900.	Fernow, 1902.	Long, 1903.	American Lumberman, 1905.
	M b'rd ft.	M board ft.	M board ft.	M board ft.	M b'rd ft.	M board ft.
White pine.....	87,755,000		50,000,000		60,000,000

Total conifers.....	420,605,100		1,090,000,000		822,682,000	1,570,000,000
Total hardwoods.....	435,685,000		300,000,000			400,000,000
Region:						
Northern States.....		100,000,000		500,000,000		
Southern States.....		300,000,000		700,000,000		
Western States.....				800,000,000		
Pacific States.....		1,000,000,000				
Total.....	856,290,100	1,400,000,000	1,390,000,000	2,000,000,000	822,682,000	1,970,000,000

* Florida and Alabama only.

The "Pacific Lumber Trade Journal," in the issue of January, 1907, gave the following estimate of the stumpage of the Pacific Coast, including Idaho, Montana, and British Columbia:

3.—ESTIMATED STUMPAGE OF CALIFORNIA, OREGON, WASHINGTON, IDAHO, MONTANA, AND BRITISH COLUMBIA.

Kind of timber.	M board feet.	Kind of timber.	M board feet.
Douglas fir	374,064,102	Spruce	25,419,215
Western and yellow pine.	175,586,520	Larch	5,078,601
Red cedar	78,961,383	Miscellaneous and hard-	
Redwood	75,000,000	woods	5,700,000
Hemlock	60,848,259		
Sugar pine	50,000,000	Total	850,658,080

This total is credited by States as follows:

	M board feet.		M board feet.
Oregon	225,000,000	British Columbia	150,000,000
Washington	195,658,080	Idaho and Montana	100,000,000
California	180,000,000		

The present annual cut of some of the principal woods is as follows: *White Pine*—about 3 billion feet in the Lake States and 1 billion feet in other States; *Yellow Pine*—about 12 billion feet, or a little more than one-third the total cut of all species, and it is evident that within 10 to 15 years there will be a most serious shortage; *Spruce*—about 1½ billion feet, of which Maine furnishes about one-third; *Hemlock*—about 3 billion feet, of which Penn., Mich., and Wis. furnish about three-fourths (the cut of both eastern spruce and eastern hemlock is decreasing, while that of western spruce and hemlock is increasing); *Douglas Spruce*—about 4½ billion feet (1½ billion feet in 1900); *Western Yellow Pine*—about 1 billion feet, two-thirds of which is in the Pacific Coast States; *Redwood*—about 450 million feet, and increasing; *Cypress*—about 750 million feet, with Louisiana supplying about 65%; *Hardwoods*—about 5 billion feet, consisting of approximately 43% oak, 12% poplar, 9% maple, and lesser amounts of numerous other species.

To engineers who are basing cost of proposed work on former estimates which are incomplete in detail, the accompanying diagram, Fig. 1, may be

Fig. 1. Range of Lumber prices, 1887 to 1907.

of interest as showing the marked advance in the prices of lumber during the past 20 years, and especially during the last decade.

Logging.—(a) *How Trees Grow.*—The section of an ordinary tree, through the trunk, discloses first the heartwood at the center, next the sapwood, and between the sapwood and the bark we find the *cambium*. If we call the bark the "coat" of the tree, we may call the cambium the (continuous) "undergarment," for it clothes every portion of the woody fiber from tip of root to end of stem, terminating in the leaves which are really an extension of the cambium itself. This slimy covering carries the life blood or sap of the tree. It has no definite thickness as it gradually merges into the bark on the one hand and into the woody fiber (sapwood) on the other. If the trunk or limb of a tree is completely girdled, exposing the cambium to the air, that portion of the tree above the girdle will die, as if amputated.

A tree breathes mainly through its leaves, and partly through the pores of the bark. The sap, containing various mineral substances as potassium, calcium, iron, sulphur, magnesium, phosphorous and nitrogen, ascends from the roots to the leaves, and is here met by the free oxygen and carbonic acid (CO_2) which the leaves breathe from the air. Various compounds, mainly *starch* ($C_6H_{10}O_5$), are formed in these chemical laboratories through the agency of the sun, and these new products, in solution, circulate back with the sap, build up the woody fiber of the tree and produce growth of trunk, roots, branches, leaves, and buds, generally. When the carbon dioxide is breathed into the leaves, much of the water of the sap is thrown off into the air, and this exhalation is called *transpiration*, a process similar to the perspiration of animals. Some trees will transpire considerably more than a hundred gallons of water in a day. When daylight ends, starch-making ceases, but the building up of the woody fibers goes on throughout the night.

Trees grow radially outward. Drive two spikes, spaced vertically, into the trunk of a tree and note that the space does not increase perceptibly as the tree grows taller. The trunk expands in diameter as the delicate cells near the cambium become thickened with starch from the down-flow sap into the woody fiber, and the up-flowing sap is forced outward through newer tubes. Finally the walls of the sapwood become hardened with mineral deposits and form heartwood. The alternate semi-annular rings are due to summer and winter growth. With the fall of the leaves the breathing takes place through the pores of the bark, and in winter the tree practically sleeps or hibernates.

(b) *Best Time for Cutting Timber.*—We usually speak of "winter cut" timber as the best, and some give as a reason, that it contains less moisture. This is hardly the case. On the contrary, some authorities claim that many woods contain quite as much if not more moisture in winter than in summer. The principal reasons why winter cut timber should be preferred are that it is harder and denser; not so susceptible to the attacks of forest fungi; and capable of being more perfectly seasoned. The most rapid growth of timber is in the early summer, and this is the poorest time for cutting. Winter and late fall cutting seasons are the best.

(c) *Volume of Standing Timber.*—The amount of standing timber on a certain tract is usually estimated by a "cruiser." This is done in various ways depending upon the accuracy required. For any individual tree, the contents is assumed equal to the area of base multiplied by one-half the height.

(d) *Transportation of Logs.*—The "felling" of trees is a very important operation, often producing splits and cracks which reduce the grade of the timber. After felling, the bark is removed and it is cut into the desired lengths for mill logs, spars, poles, piles, ties, etc. Mill logs are usually in even lengths, from 12 ft. upward, generally from 16 to 34 ft. They are dragged, rafted, flumed, or shipped (by logging trains) to the mill. Ocean rafts are sometimes made up at an expense of many thousands of dollars, and towed hundreds of miles to save the cost of rail transportation. These rafts are cigar shaped, composed of the longest obtainable logs, arranged scientifically with "broken joints," and well bound with heavy chains for strength in resisting the action of the heavy seas. If this method is contemplated, it is wise to *estimate*, ordinarily, that one raft in every two or three is liable to be "broken up" and lost. Successful rafting of this kind has been performed from Astoria, Oregon, to San Francisco, and from Nova Scotia to Jersey City, N. J.

(e) *Scaling Logs*.—The determination of the number of thousand feet of lumber in logs, as a basis for selling, is usually made at the mill by an official scaler. The diam of the small end is measured in ins. by a scale rule, 4 ins. deducted, and the balance squared. The result is the number of ft. B. M. for a log 16 ft. in length—proportionate for logs of other lengths. Where logs are defective a reduction is made depending upon the judgment of the scaler.

Sawing the logs up into rough lumber, such as "sticks" (general term for large dimension timber), posts, beams, joists, ties, scantling (small dimension stuff), boards, shingles and laths, is done with the various saws, as band, circular (single or double), slab, gang, shingle, and lath saws. Rough lumber should be furnished "full-dimension" but not necessarily to exact dimension, as ordered. When exact dimensions are required the lumber should be ordered "sized."

"Sizing" consists in running the rough lumber through the planer or "sticker," so gaged that when planed it shall be exactly to ordered dimensions. In ordering say $12'' \times 12''$ to be planed on *all* sides, we generally say $12'' \times 12''$ s 4 s; if on *one* side, $12'' \times 12''$ s 1 s; etc.

Planing costs the purchaser, ordinarily, from \$1.50 to \$2.00 per M, but it is often desirable to order planed lumber where rough lumber might answer; thus, with so-called "permanent" wooden structures like Howe truss bridges, for instance, the cost of framing with planed lumber is less than with rough, and the life greater, to say nothing of the appearance. Rough dimension stuff which is to be planed is usually ordered about $\frac{1}{4}''$ large for each dimension, depending upon size of piece; less for smaller pieces.

Seasoning.—After being sawed, lumber should be seasoned more or less thoroughly before being used. If "open-stacked" under roof shelter for three months or longer it is in fairly good condition for ordinary outside construction, but for so-called thoroughly dried lumber a year or two is required. Heavy timbers of course require longer periods. Kiln-dried lumber is the common practice and is very satisfactory if properly done, and the temperature of the kiln is not too high. If steam is admitted the temperature may be from 160° to 170° F. for the harder woods and from 170° to 180° for the softer kinds, as pine. In dry kilns the temperature should be lower. The harder woods are preferably stacked in the open air for some months before being placed in the kilns, or they may be immediately kiln dried at low temperatures. (See also "Seasoning of Timber," under Preservatives, page 361).

Board Measure.—One ft. B. M. of lumber is equivalent to a board 1 in. thick, 12 ins. wide, and 1 ft. long, or $\frac{1}{12}$ cu. ft.; hence 1000 ft. B. M. (= 1 M. B. M.) contains $83\frac{1}{3}$ cu. ft.

The following Table (4) of board measure embraces all the sizes ordinarily used in construction, and gives the ft. B. M. for lengths from 1 to 9, which may be used decimally for any lengths. Interpolation may be resorted to for dimensions not in the table, but this will rarely be necessary. Another method is to find the ft. B. M. for dimensions 2 or more times as large or small, and then factor the results accordingly. Note that for this purpose the list of 1-inch stuff is very comprehensive.

Where (exact) results are required to decimal places beyond those in the table—which will rarely be the case—a casual inspection will in most cases suffice. Thus, $1.083 = 1.083 \times 3$, $3.167 = 3.16 \times 6$, $1.042 = 1.0416 \times 6$, etc. The "character" of the decimal for any particular length may generally be determined by examining other decimals in the same *line*, showing whether the decimal represents 6ths, 8ths, 12ths, 16ths, etc.

*Ex.—Find the number of ft. B. M. in 2438 lin. ft. of $1\frac{1}{2} \times 6\frac{1}{2}$?

Solution.—2000 = 1083.3

400 = 216.7

30 = 16.25

8 = 4.333

Ans.—1321. ft. B. M.

Grading of Lumber.—Attention is here called to Forest Service Bulletin 71, U. S. Dept. of Agriculture, entitled "Rules and Specifications for the Grading of Lumber, adopted by the Various [18] Lumber Manufacturing Associations of the U. S." Compiled by E. R. Hodson, 1906.

The American Society for Testing Materials has undertaken the very difficult task of recommending Standard Specifications for the Grading of Structural Timber. The report of the Committee for 1906 will be found in Vol. VI of the proceedings, page 129, and is discussed under three headings: (1) Definitions of structural timber, (2) Standard defects, and (3) Standard names for structural timbers. Among the standard defects are the following: *Sound knot*—solid across its face, and as hard as the surrounding wood; *loose knot*—not firmly held in place by growth or position; *pith knot*—sound knot with pith hole not more than $\frac{1}{4}$ in. in dia in the center; *rotten knot*—not as hard as the surrounding wood; *pin knot*—sound knot not over $\frac{1}{4}$ in. in dia.; *large knot*—sound knot more than $1\frac{1}{2}$ ins. in dia.; *spike knot*—one sawn in a lengthwise direction; *pitch pockets*—openings in grain of wood containing more or less pitch or bark (*small* when not over $\frac{1}{4}$ in. wide, *standard* when not over $\frac{1}{2}$ in. wide or 3 ins. long, *large* when over $\frac{1}{2}$ in. wide or 3 ins. long); *wane*—bark or lack of wood on edge of timber; *shakes*—splits or checks between annular rings; *rot*, *dots*, and *red heart*—white or red rotten spots, dark discolorations not found in sound wood, etc.

Classification and Inspection of Yellow Pine Lumber.*—General Rules.—All lumber must be sound, commercial longleaf yellow pine (pine combining large coarse knots, with coarse grain, is excluded under these rules), well manufactured, full to size and saw butted, and shall be free from the following defects: Unsound, loose, and hollow knots, wormholes and knot holes, through shakes or round shakes that show on the surface; and shall be square edge unless otherwise specified. A through shake is hereby defined to be through or connected from side to side, or edge to edge, or edge to side. In the measurement of dressed lumber the width and thickness of the lumber before dressing must be taken—less than one inch thick shall be measured as one inch. The measurement of wane shall always apply to the lumber in the rough. Where terms one-half and two-thirds heart are used they shall be construed as referring to the area of the face on which measured.

* Interstate rules of 1905. Adopted by the Georgia-Florida Sawmill Association, Georgia Interstate Sawmill Association, South Carolina Lumber Association, New York Lumber Trade Association of New York City, Yellow Pine Exchange of New York City, The Lumbermen's Exchange of Philadelphia, The Lumbermen's Exchange of Baltimore.

In the dressing of lumber, when not otherwise specified, one-eighth inch shall be taken off by each planer cut. All lumber grading higher than the grade for which it is sold shall be accepted as of the grade sold.

Classification.—*Flooring* shall embrace four, five and six quarter inches in thickness by three to six inches in width, excluding $1\frac{1}{2} \times 6$. For example, 1×3 , 4, 5, and 6; $1\frac{1}{2} \times 3$, 4, 5, and 6; $1\frac{1}{2} \times 3$, 4, and 5. *Boards* shall embrace all thicknesses under $1\frac{1}{2}$ ins. by over 6 ins. wide. For example: $\frac{3}{4}$, 1, $1\frac{1}{2}$, and $1\frac{1}{2}$ ins. thick by over 6 ins. wide. *Plank* shall embrace all sizes from $1\frac{1}{2}$ to under 6 ins. in thickness by over 6 ins. in width. For example: $1\frac{1}{2}$, 2, $2\frac{1}{2}$, 3, $3\frac{1}{2}$, 4, $4\frac{1}{2}$, 5, $5\frac{1}{2}$, $5\frac{1}{2}$, by 6 and over in width. *Scantling* shall embrace all sizes exceeding $1\frac{1}{2}$ ins. and under 6 ins. in thickness, and from 2 to under 6 ins. in width. For example: 2×2 , 2×3 , 2×4 , 2×5 , 3×3 , 3×4 , 3×5 , 4×4 , 4×5 , and 5×5 . *Dimension sizes* shall embrace all sizes 6 ins. and up in thickness by 6 ins. and up in width. For example: 6×6 , 6×7 , 7×7 , 7×8 , 8×9 , and up. *Stepping* shall embrace 1 to $2\frac{1}{2}$ ins. in thickness by 7 ins. and up in width. For example: 1, $1\frac{1}{2}$, $1\frac{1}{2}$, 2, and $2\frac{1}{2} \times 7$, and up in width. *Rough Edge or Flitch* shall embrace all sizes 1 in. and up in thickness by 8 ins. and up in width, sawed on two sides only. For example: 1, $1\frac{1}{2}$, 2, 3, 4, and up thick by 8 ins. and up wide, sawed on two sides only.

Inspection.—*Standard* lumber shall be sound, sap no objection. *Wane* may be allowed $\frac{1}{4}$ of the width of the piece measured across face of wane, extending $\frac{1}{4}$ of the length on one corner, or its equivalent on two or more corners, provided that not over 10% of the pieces of any one size shall show such wane. *Merchantable* sizes under 9 ins. shall show some heart the entire length on one side; sizes 9 ins. and over shall show some heart the entire length on two opposite sides. *Wane* may be allowed $\frac{1}{4}$ of the width of the piece measured across face or wane, and extending $\frac{1}{4}$ of the length of the piece on one corner or its equivalent on two or more corners, provided that not over 10% of the pieces of any one size shall show such wane. *Prime* lumber.—*Flooring* shall show one heart face, free from through or round shakes or knots exceeding one inch in dia or more than four in a board on the face side. *Boards* 7 ins. and under wide shall show one heart face; over 7 ins. wide shall show $\frac{1}{2}$ heart on both sides; all free from round or through shakes, large or unsound knots. *Plank* 7 ins. and under wide shall show one heart face; over 7 ins. wide shall show $\frac{1}{2}$ heart on both sides; all free from round or through shakes, large or unsound knots. *Scantling* shall show three corners heart, free from through or round shakes or unsound knots. *Dimension sizes of Prime lumber.*—All square lumber shall show $\frac{1}{2}$ heart on two sides and not less than $\frac{1}{4}$ heart on two other sides. Other sizes shall show $\frac{1}{2}$ heart on face and show heart $\frac{1}{4}$ of length on edges, excepting when the width exceeds the thickness by 3 ins. or over; then it shall show heart on the edges for $\frac{1}{4}$ the length. *Stepping* shall show 3 corners heart, free from shakes and all knots exceeding $\frac{1}{4}$ in. in dia, and not more than 6 in a board. *Rough Edge or Flitch* shall be sawed from good heart timber, and shall be measured in the middle on the narrow face, free from injurious shakes or unsound knots. *Wane* on not over 5% of the pieces in any one size, shall be allowed as on merchantable quality.

Rules for Grading Fir, Spruce, Cedar, and Hemlock Lumber.*—General Instructions.—All lumber graded with special reference to its suitability for the use intended; therefore each piece is considered and its grade determined by its general character, including the sum of all its defects. "Yard Lumber" (dimension, common boards, finish, etc.) is graded from the face (best) side, except that when lumber which is dressed one side only is graded from the dressed side. *Factory lumber* (for doors, sashes, etc.) which must show on both sides, is always graded from the poorest side. Defects are taken in connection with the size of the piece, wider and longer pieces carrying more defects than smaller pieces in the same grade. Grade is determined at time of shipment and cannot be reconsidered after further working; a shipment of any grade to consist of a fair average of that grade. Material not conforming to standard sizes shall be governed by special contract. Standard lengths for all lumber are multiples of two feet, except that the standard lengths for flooring, ceiling, siding, rustic, and finish are

* Rail shipments. Digest of rules adopted March 30, 1906, by the Pacific Coast Lumber Manufacturers' Association, Southwestern Washington Lumber Manufacturers' Association, Oregon and Washington Lumber Manufacturers' Association.

ot. Odd and fractional lengths shall be counted as next length. All dressed lumber shall be measured and sold rough material used in its manufacture; and lumber one kness shall be counted as one inch thick.

nized defects are knots (classed as sound or loose, ot holes, splits and checks (considered as to length and ark or lack of wood from any cause on edges of timber), rm holes, pitch seams (clearly defined openings between wood, are generally filled with granulated pitch, and a not admissible in any grade above No. 2 Common), aings between the grains of the wood containing more or ounded by sound grain wood), torn or chipped grain dressing against the grain and is more or less of a defect th or extent), discoloration (the result of various causes, onsidered a defect when the piece is damaged for the

-Defects in rough stock caused by improper manufac- l reduce the grade, unless they may be removed by dress- standard sizes. Imperfect manufacture in dressing n grain, broken knots, mismatching, insufficient tongue ng, ceiling, drop siding, etc., shall be considered defects grade accordingly as they are slight or serious in their the stock.

FIR.

d sorted with reference to the direction of the grain. ain) has the grain at or nearly at right angle with face adapted to flooring, stepping, etc., because it does not r. F. G. (flat grain) means that the grain is parallel or the face of the board; it is selected for finish because of orm.

1 Clear E. G., 3, 4 and 6 in.; free from all defects; angle an 45°. No. 2 Clear E. G., 3, 4 and 6 in.; angle of grain will admit of slight roughness in dressing, and from 1 to pockets, or equivalent defects. No. 3 Clear E. G., 3, of grain not less than 45°; such defects admitted as will ty for cheap floors. No. 1 Clear F. G., 3, 4 and 6 in.; s, and all flat grain. No. 2 Clear F. G., 3, 4 and 6 in.; will admit of slight roughness in dressing, three close o exceed 2 ins. in length, and 3 small tight smooth knots equivalent of combined defects. No. 3 Clear F. G., 3, defects admitted as will not impair its utility for cheap g.

3 inch, Classed as No. 1 Clear, No. 2 Clear, No. 3 Clear; G. admissible.

6 inch. Graded same as Ceiling on the face side with t more than one grade lower.

Drop Siding, and Rustic.—Classed as No. 1 Clear (6 or 4, 6 or 8 in.), No. 3 Clear (4, 6 or 8 in.).

4 and 6 inch. Classed as No. 1 Clear, No. 2 Clear, No. 3

sed as No. 1 Clear (8 to 14 inch Clear), No. 2 Clear

ling.—Generally speaking, there should be no imper- usly impair the strength of the piece.

—4x4 and larger shall not be more than $\frac{1}{4}$ inch scant e evenly manufactured from sound stock, and must be at would materially weaken the piece. Timbers 10x10 2 inch wane on one corner, or its equivalent on two or fourth the length of the piece. Other sizes may have cts. Season checks and checks extending not over gth of the piece admissible.

SPRUCE.

Names and Grades.—Flooring is classed as Clear, "A," and "B;" Finish, as First and Second Clear, Third Clear, Selects; Ceiling, as Clear, "A," and "B;" Partition, as Clear, "A," and "B;" Porch Decking, as Clear, "A," and "B;" Bevel Siding, as Clear, "A," "B," and "C;" Factory Stock, as Select and Better, No. 1 Shop, No. 2 Shop.

RED CEDAR.

Names and Grades.—Bevel Siding is classed as Clear, "A," and "B;" Ceiling, as No. 1, No. 2, No. 3; Finish, as No. 1, No. 2, No. 3; Corrugated Decking, as No. 2 and Better; Flooring, as No. 1, No. 2, No. 3.

HEMLOCK.

In a general way the rules for grading Fir and Spruce lumber are applied to Hemlock.

Shingles.†—*Perfections.*—18 inch, random widths, five butts must measure $2\frac{1}{2}$ inch plump in thickness when green, or $2\frac{1}{2}$ inches after drying. Must be well manufactured, strictly clear in every respect, and 90% vertical grain. Will not admit any shingle narrower than 3 inches.

Puget A.—Same thickness as Perfections. Must be well manufactured; will admit sound knots 8 inches from butt, 16-inch shims; also admits slash-grain shingles, otherwise must be clear. Will not admit shingles narrower than 2 inches.

Eureka.—18 inch, random widths, five butts must measure $2\frac{1}{2}$ inches in thickness when green, or 2 inches after drying. Must be well manufactured, strictly clear in every respect, and 90 per cent vertical grain. Will not admit any shingles narrower than 3 inches.

Skagit A.—Same thickness as Eureka. Must be well manufactured. Will admit sound knots 8 inches from butt; 16-inch shims. Also admit slash-grain shingles; otherwise must be clear. Will not admit shingles narrower than 2 inches.

Extra Clear.—16 inch, random widths, five butts must measure $2\frac{1}{2}$ inches in thickness when green, or 2 inches after drying. Must be well manufactured, strictly clear in every respect, and 90 per cent vertical grain. Will not admit any shingles narrower than 2 inches.

Choice A.—Same width and thickness as Extra Clear. Must be well manufactured. Will admit sound knots 6 inches from butt; also slash-grain shingles, wane edge, sap, 14-inch shims, $\frac{1}{2}$ -inch knotholes or worm holes 6 inches from butt; otherwise must be clear.

*Extra *A**—16-inch random widths, six butts must measure $2\frac{1}{2}$ inches green, or 2 inches after drying; must be well manufactured. Will admit sound knots 10 inches from butt; otherwise must be strictly clear, and 90 per cent. vertical grain. Will not admit any shingles narrower than 2 inches.

Standard A.—Same width and thickness as Extra *A*^{*}; must be well manufactured. Will admit sound knots 6 inches from butt, slash-grain shingles, wane edge, sap, 14-inch shims, $\frac{1}{2}$ -inch knot holes or more holes 6 inches from butt; otherwise must be clear.

Shingles with the following defects are *culls*, and must not be put in any of the above grades: Rot, worm holes, except as above provided, check, shake, stub corners, tapering edges, rough, waney, or unevenly sawn.

Eighteen inch, 5 to $2\frac{1}{2}$ inch shingles, must be packed 20 courses per bunch, 5 bunches to the M. Eighteen inch, 5 to 2 inch, and 16-inch shingles, must be packed 25 courses to the bunch, 4 bunches to the M. All shingles must be packed in the regulation frame, full 20 inches in width, and no opening of more than $1\frac{1}{2}$ inches is admissible in any one course.

All shingles to be packed as closely as possible. Bands should not be shorter than $19\frac{1}{2}$ inches in length. Every bunch of shingles must be branded.

Dimension shingles are packed 24 courses in each bunch.

† Oregon and Washington Lumber Manufacturers' Association.

EXCERPTS AND REFERENCES.

Graphical Comparison of Various Log Rules (By A. H. Morse. Eng. News, April 9, 1908).—According to The Woodman's Handbook, by Prof. H. S. Graves, published as Bulletin 36 of the Bureau of Forestry, U. S. Dept. of Agric., Wash., D. C., more than 30 different "log rules" are in use in the U. S. All these rules profess to accomplish the same thing, viz., to provide means for ascertaining the number of board feet of 1-in. lumber which can be sawn from a log of given dia. and length; that is, to give the "scale" of a log in board feet. This article compares the principal log rules.

A Table of Lumber Weights (Eng. News, May 5, 1910).—The following table of weights of lumber represents the commercial classification, taken from the reports of the secretaries of the various lumber associations, and are accepted by the trade in place of actual weights.

21.—METALLURGY.

Iron Ore.—Hematite (Fe_2O_3), an ore abundant around Lake Superior, in Alabama, etc., furnishes five-sixths of the iron manufactured in the United States; with limonite (one-ninth), and magnetite (one-sixteenth), next in order. Most of the ore has to be prepared for the blast-furnace. Thus, "sorting" the ore from foreign fragments; "washing" away the earthy matter; "concentrating" the crushed ore by magnetic "separators;" "calcinating" or driving off the volatile matter by heat; etc., are methods usually employed. Iron ore contains from 35 to 65% of iron, the balance being oxygen, phosphorus, sulphur, silica (sand), and other impurities.

Pig Iron is the cast iron product from a blast furnace. The furnace is shaped like a lamp chimney, and the charge is introduced at the top: layers of ore, limestone, fuel, ore, limestone, fuel*, etc., in regular sequence. By forcing a current of hot air at the bottom of the furnace into the heated mass a series of chemical reactions take place, producing molten iron, molten slag, and gases. The molten iron is drawn off after the slag and run into moulds or (cast) pigs.† From pig iron all kinds of iron and steel can be made. Among the uses to which pig-iron may be put are the following:

- (a) Directly without refining, for foundry work.
- (b) Refined by elimination of silica and phosphorus, then removal of carbon by dry-puddling, for wrought iron (not used in U. S.).
- (c) Wet puddling, in removal of silica, phosphorus and carbon, for soft structural and blacksmith iron.
- (d) Acid Bessemer, in removal of silica, manganese and carbon, for rails and structural steels (mild).
- (e) Basic Bessemer, in removal of silica, manganese, carbon and phosphorus, for rails and structural steels (mild).
- (f) Krupp washing, and Siemens-Martin process, for structural steels (mild).
- (g) Charcoal hearths, for wrought iron; cementation furnace, for shear steel; crucible, for high grade tool steel.

Cast Iron.—In foundry work, for ordinary castings, the melt from the cupola is much more certain in composition than the direct casting from the unrefined pig. It gives a closer grain and somewhat increased strength. A good casting contains about 3.5 per cent. carbon, 1.5 per cent. silicon, not over 0.7 per cent. phosphorus, 0.6 per cent. manganese, and a trace of sulphur. It shows a gray fracture, can be worked easily with chisel and file, completely fills the mold, chills with a smooth surface, has no blow holes, shrinks little in cooling. Large castings should contain less silicon than small; shrinkage may be decreased by lowering the manganese; to increase the strength the carbon, silicon and manganese are lowered and phosphorus eliminated as far as possible.

The above chemical properties may be varied to suit the special purposes for which the castings are intended. Mr. Henry Souther,‡ in Vol. V, Proc. A. S. T. M., page 218, says with reference to Hard Cast Iron which had given complaint in the machine shop: "Cast iron that chills may be called hard in the truest sense of the word. . . . In the last five or six years three separate complaints of hard iron have reached the writer and proved of so baffling a character that in each case visits were made to the machine shops. . . . It developed [citing one particular case] that small drills, $\frac{1}{4}$ -in. or thereabout, were standing up with this iron just as well as any other, but the larger drills in the neighborhood of $\frac{1}{2}$ -in. and $\frac{3}{4}$ -in. were dulling exactly as though the iron were charged with emery.

* Charcoal, coke or anthracite coal.

† Pig iron contains about 93% of pure iron, 3 to 5% of carbon (pure coal), also some silicon, phosphorus, sulphur, etc.

‡ State Chemist, Hartford, Conn.

The edges were being ground off and would last only a fraction of the time usual for the same drills in the same machine. Here was an unusual condition, thin iron working easily, thick iron on the same castings working with difficulty. The chemical results were normal, except manganese: Silicon 2.50, phosphorus .70, sulphur about .08, total carbon 3.50 and manganese .10. . . . Inasmuch as the only abnormal part in the analysis was shown in the manganese, that element was suspected, although there seemed to be no metallurgical reason for doing so. Means were taken to raise it to the neighborhood of .50, and as soon as this was done the difficulty disappeared in the machine shop and has not reappeared after some months. . . . This leads to the belief that there must be some carbide of iron or carbide of silicon that forms in the absence of a reasonable amount of manganese, and that does not form with manganese present."

Cast Steel.—*Steel for castings, may be made by the open-hearth, crucible or Bessemer process. Castings to be annealed unless otherwise specified. Ordinary castings, those in which no physical requirements are specified, shall not contain over 0.40% carbon, nor over 0.08% phosphorus. Castings which are subjected to physical test shall not contain over 0.05% phosphorus, nor over 0.05% sulphur.

Tested castings shall be of three classes: Hard, Medium, and Soft, with minimum physical requirements as follows:

	Hard.	Medium.	Soft.
Tensile strength, lbs. per sq. in.	85000.	70000.	60000.
Yield point,	38250.	31500.	27000.
Elongation, per cent in two ins.	15.	18.	22.
Contraction of area, per cent.	20.	25.	30.

For determining the above physical properties, standard turned specimens $\frac{1}{2}$ " in dia. and 2" gauged length shall be used.

For bending test, a specimen $1\frac{1}{2}$ " shall bend cold around a dia. of 1" without fracture on outside of bent portion, through an angle of 90° for "Medium" or 120° for "Soft" castings.

Malleable Castings.—An ordinary casting, unless it is too large, may be made malleable by decarburization. The original casting is preferably "white," indicating that it is low in carbon, and should practically be free from sulphur and phosphorus. The castings are packed in a pot (or retort) with oxide of iron, usually hematite, placed in a furnace, and kept at an orange or red heat for about a week, and then cooled very slowly. The carbon in the casting mostly unites with the oxygen of the ore, passing off as carbonic oxide. The casting is thus rendered malleable like crude wrought iron. Malleable castings are used for pipe specials which have to be threaded; for wood-stave (water) pipe shoes; and in general for delicate castings which are liable to be subjected to various kinds of stress.

Wrought Iron.—Wrought iron is purified pig iron. Although it is made "directly" from the ore the "indirect" process is generally used. The pig iron is oxidized in a puddling furnace whence the silicon, manganese, phosphorus and carbon impurities are removed. As with malleable cast iron the light grades, containing the least carbon and those practically free from sulphur and phosphorus, are selected. The wet-puddling process, in a reverberatory furnace, is the practice in the United States. A gray unrefined iron, containing more silica than the white, is used, mixed with a large quantity of hematite or magnetite of high grade used as reagents for oxidizing the impurities—the carbon passing off in the resulting carbon dioxide, and the other impurities, in the slag. The following shows the per cent. of composition of the pig and of the resulting muck-bar (puddle bar), in a typical case:

	Carbon.	Man- ganese.	Silicon.	Phos- phorus.	Sulphur.
Pig (before melting). 2.55%	5.15%	3.20%	0.95%	0.05%	
Muck-bar iron. 0.65"	0.15"	0.10"	0.10"	0.01"	

* Synopsis of Specifications adopted by letter-ballot of the A. S. T. M. on Sept. 1, 1905.

The objection to this process is the enormous cost of fuel. The muck bars are re-heated and rolled into merchant bar—principally demanded by the blacksmith. (Soft or mild steels are generally replacing wrought iron.)

Mr. George Schuhmann, in the "Pilot" (official publication of the P. & R. Ry. Dept.), April, 1906, says:

"The purer the iron the higher is its melting point. Pig iron melts at about 2100 degrees F., steel at about 2500 degrees, and wrought iron at about 2800 degrees. The temperature in the puddling furnace is high enough to melt pig iron, but not high enough to keep wrought iron in a liquid state; therefore, as soon as the small particles of iron become purified they partly congeal (come to nature), forming a spongy mass in which small globules of iron are in a semi-plastic state, feebly cohering with fluid cinder filling the cavities between them. This sponge is divided by the puddler into lumps of about 200 lbs. each; these lumps or balls are taken to a steam hammer or a squeezer, where they are hammered or squeezed into elongated blocks (blooms), and while still hot, rolled out between the puddle rolls into bars 3 to 6 inches wide, about $\frac{1}{2}$ -inch thick, 15 to 30 ft. long. These bars are called puddle bars or muck bars, and, owing to the large amount of cinder still contained therein, they have rather rough surfaces. The muck bars are cut up into pieces from 2 to 4 ft. long and piled on top of each other in so-called "piles" varying from 100 to 2000 lbs., according to the size product desired. These piles are heated in heating furnaces, and when white hot, are taken to the rolls to be welded together and rolled out into merchant iron in the shape of either sheets, plates, bars, or structural shapes as desired. When cold this material is sheared and straightened, and is then ready for the market.

After leaving the puddle furnace, wrought iron does not undergo any material change in its chemical composition, and the only physical change is an expulsion of a large portion of the cinder; the small cinder-coated globules of iron are welded together and the subsequent rolling back and forth will elongate these globules, giving the iron a fibrous structure, and reheating and rerolling will drive these fibers closer together, thus increasing the strength and ductility of the metal.

Steel—For structural work, steel has almost entirely superseded wrought iron, being stronger and more cheaply manufactured. The latter, however, is still used largely for underground pipes, because better able to resist decomposition by the natural elements and also electrolysis. The following typical analyses of the products of the four principal processes of structural steel manufacture are here shown for approximate comparison, being in no way absolute:

	Acid Bessemer.		Basic Bessemer		Acid Open Hearth.		Basic Open Hearth.
	Soft S.	Rail S.	Soft S.	Med. H'd S.	Soft S.	Rail S.	
Combined carbon	.12%	.43%	.16%	.75%	.12%	.43%	.14%
Silicon.....	.04	.06	.06	.20		.01	
Sulphur.....	.05	.06	.04	.04	.05	.06	.04
Phosphorus....	.06	.07	.04	.04	.06	.07	.05
Manganese.....	.06	.50	.50	.70	.60	.80	1.20
Arsenic.....	.04	.05	.04	.04	.04	.04	.04

These processes consist in decarburizing and purifying the pig iron to a practically pure liquid wrought iron; recharging the liquid with carbon and manganese where necessary; and casting it into ingots. They will be described as briefly as possible.

Acid Bessemer Process.—The molten iron or pig from the blast furnace (direct process) or the cupola (indirect process) is poured into an "acid" lined "converter," in the bottom of which are a number of small holes

through which air is forced into the metal. The air oxidizes to impurities—carbon, silicon, manganese, etc.—the heat of combustion from the carbon and sulphur maintaining the metal in a fluid condition. The "acid" lining is a highly refractory, siliceous (about 93 per cent. silica) material, which removes the carbon, silicon and manganese, but is incapable of taking the phosphorus and sulphur away from the metal; hence the pig iron used must practically be free from these two latter elements, as they are not allowed to enter largely into steel. The impurities being thus removed it is now liquid wrought iron. Carbon, for strength and hardness, and manganese, for malleability in rolling, are added—the latter in the form of spiegeleisen or ferro-manganese. It is now steel and is poured into molds for cooling down into ingots. These ingots are charged into the soaking pit or vertical furnace to equalize before being rolled into blooms. Later, the blooms are (re-heated and) rolled into rails or into the various structural shapes desired.

Basic Bessemer Process.—Pig iron that is too high in phosphorus (2.5 to 3.0 per cent.) for the acid Bessemer process may be converted into steel by the basic Bessemer process provided it is low (below 0.50 per cent.) in silicon. The "basic" lining of the "converter" is made from a pure magnesian limestone (dolomite) containing about 20 per cent. of magnesia, but not over 1 or 2 per cent. of silica. The pig is usually remelted in the cupola and transferred to the converter—hard-burned limestone low in SiO_2 being added as a flux—where air is introduced as in the acid process. The impurities in the metal are burned out, the phosphorus furnishing the heat and uniting with the lime to form phosphate of lime. The liquid is now almost a chemically pure iron, and is recarburized as in the acid Bessemer process. The floating slag when cooled and ground is used as a fertilizer or for cement.

This process is not used much in the U. S.

Acid Open Hearth Process.—This process, like the acid Bessemer, calls for a pig low in sulphur and phosphorus because neither is eliminated. The Siemens furnace is a large hearth built of refractory siliceous material on which the metal is melted, by the combustion of gas admitted into the furnace alternately with air. No solid fuel is used. A typical pig iron would contain about the following: Carbon 3.5 per cent., silicon 2.2, sulphur 0.03, phosphorus 0.035, manganese 0.75.

This process is particularly adapted to producing steels high in carbon and to the exact percentages specified.

Basic Open Hearth Process.—In this process the lining of the hearth is made from the "basic" material—magnesian limestone—and like the basic Bessemer, a high phosphoric pig is used, say about as follows: Phosphorus, 1.80 per cent.; silicon, not over 1.50; sulphur, not over 0.50; manganese, 1.75; carbon, 3.50. Iron and steel scrap is also added to the melt. The method is about the same as for the acid O-H process, the impurities being separated from the bath partly by the air admitted and partly by the addition of iron oxides. The product is an excellent steel.

Cementation Process.—This process is still employed in making high grade carbon steels for tools, cutlery, etc. "Cement bars" are made from the purest and best grade iron (usually the Swedish) heated in contact with carbon (charcoal) to a red heat maintained for a week or more. The product is called "cement steel" or "blister steel." "Shear steel" is made from cement steel by cutting, piling, heating and rolling the cement bars—"double shear steel" being simply a duplication of the process. "Crucible steel" or "cast steel" is made from blister steel by cutting up and melting the bars in a black-lead pot, and cooling in the form of ingots.

Shear steel is used for plows and cheap edge tools, but not for high grade tools.

Crucible cast steel, made by melting the blister steel of the cementation process in crucibles, is a high grade steel, used for the best tools. In order to avoid the permanent set of internal stresses in castings, due to unequal shrinkage in cooling, they are "annealed" by being gradually

heated to temperatures between 800° (for high carbon steel) and 900° (for low carbon steels). Crucible steel is "tempered" for different uses, depending upon the percentage of carbon present, as follows:

Name of Temper.	Per cent. of Carbon.	Burning.	Welding.	Temper.	Remarks.
Razor ..	1.5	Easy.	Very difficult.	Extremely hard.	Razors, etc.
Saw-file	1.375			Hard.	Saws, etc.
Tool....	1.25		Possible.		Extreme care required in welding.
Spindle..	1.125			Medium.	Machine turning tools, cutters, etc.
Chisel ..	1.		Quite easy.		Cold chisels, hot sets, etc.
Set.....	0.875			Little.	Cold sets, etc.
Die.....	0.75	Noteasy.	Easy.	Very little.	For hard surface tools as dies.

Steels very low in carbon can easily be welded but not tempered. Steel with carbon above $\frac{1}{4}$ per cent. can be tempered by heating to a high heat, and then quenching in water or other liquid.

Open Hearth Cast Steel.—The *acid* open hearth is generally preferred. The cast steel produced is adapted to machinery castings for steel vessels, cars, etc.; it contains from one-sixth to one-half of one per cent. carbon.

Harveyized steel plates for armor are mild steel plates, face-hardened on one side by carburization and sudden chilling; the other side may remain as mild steel or be decarburized into a softer metal.

Manganese steel is a steel containing about 14 per cent. manganese, and is made by melting ferro-manganese with carbon steel. It is very tough and hard, capable of being forged. It is used principally for car wheels, stamp heads and jaws for crushing machines; also for crossing frogs.

Vanadium steel is used for crusher jaws, gear wheels, etc. (See also page 399.)

Chrome steel is made by melting ferro-chrome with bar iron, in a crucible. It is very hard and can be forged readily. Contains about 1.8 per cent. chromium and 0.7 per cent. carbon.

Nickel steel is produced by adding nickel ore to the carbon steel in the open hearth bath, thus increasing the strength and elasticity. It is used in armor plate manufacture; and, with the probable future reduction in cost, will doubtless be used in steel bridges, especially of long spans, in the near future. (See, also, pages 398 and 399.)

Tungsten steel is very hard, difficult to forge, and is used for cutting-tools.

Alloys.—An alloy is a mixture of two or more metals by fusion. The number of possible mixtures, taking into consideration the varying proportions, is infinite, but the principal alloys useful to the engineer, are to a certain extent limited and well known. From a mechanical point of view the most useful metals for alloys are: copper (Cu), tin (Sn), zinc (Zn), lead (Pb), antimony (Sb), nickel (Ni), bismuth (Bi), aluminum (Al), iron (Fe), etc., about in the order mentioned. Cu is by far the most useful and may be classed as the primary metal; with Sn, Zn, Pb, and Sb, secondary; and Ni, Bi, Al, Fe, etc., tertiary, as follows:

Fe	Sn	Al
Pb	Cu	Sb
Ni	Zn	Bi

Bronze (*Cu, Sn, X*) is the name generally given to those alloys consisting chiefly of copper and tin, with the former metal largely in excess. The following are some of the principal bronzes and their uses:

Name.	Composition (parts).			Remarks.
	Copper.	Tin.	Other metals.	
Medal B.....	95	5		
Coin B.....	91	9		
Gun B.....	90	10		For navy ordnance.
Statuary B.....	89	11		
Valve-metal.....	88	12	Zinc (2).	
Bell-metal.....	82	18		
Speculum-metal...	68	32		

Phosphor bronze is a bronze containing a small percentage (3±) of phosphorus properly introduced during fusion. It materially increases the strength and hardness of the metal and renders it less susceptible to oxidation and the action of the elements generally. Phosphor bronze is used for heavy journal bearings in the best machinery, and for wire.

Manganese bronze (*Cu, Sn, Mn*) is a bronze containing a small percentage (1+) of manganese, rendering the material tough and non-corrosive. It is largely used for propeller blades. A good mixture is *Cu* (88), *Sn* (10), *Mn* (2).

Aluminum bronze (*Cu, Al*), so-called, is usually composed of *Cu* (90) and *Al* (10) although these proportions may be varied greatly. It has a high tensile strength and is not easily corroded.

Silicon bronze (*Cu, Sn, Si*) is used for castings and for telegraph wires. It is an excellent conductor of electricity and has great tensile strength. The proportion of silicon is from 3 to 5 per cent. Tin may or may not be used with the copper.

Brass (*Cu, Zn, X*) includes the alloys which are composed mainly of copper and zinc. The principal ones are tabularized as follows:

Name.	Composition (parts).			Remarks.
	Copper.	Zinc.	Other metals.	
Valve-metal.....	83	15	Tin (2).	
Brazing-metal.....	75	25		Flanges for copper pipe.
.....	70	30		Works well under hammer.
Common B.....	67	33		
Muntz-metal.....	60	40		
Delta-metal.....	58	40	Iron.	
Tobin "Bronze" ..	58	40	Tin, lead, iron.	
Thurston-metal. .	56	42	Tin (2).	Thurston's maximum is 57, 42, 1.
Brazing-metal.....	50	50		Solder for copper pipe flanges.
German silver.....	60	20	Nickel (20).	

Tin-base Alloys.—

Name.	Composition (parts).				Remarks.
	Tin.	Zinc.	Lead.	Other Metals.	
Babbitt-metal..	89			{ Sb, 8 Cu, 8	Used for machinery bearings.
Pewter.....	85			15	Contains antimony, copper and bismuth.
Solder.....	67	33			
".....	50		50		

Lead-base Alloys.—

Name.	Composition (parts).				Remarks.
	Lead.	Tin.	Anti-mony.	Bis-muth.	
White-metal....	88		12		
Fusible plug....	86	10		4	For steam boilers

Alzene, a new metal alloy composed of aluminum and zinc, is said to be as strong as cast iron, much more elastic, does not rust easily, and takes a very high polish. It is a German product. Future results of investigations are awaited with interest. The present proportions of the alloy are 2 parts aluminum and 1 part zinc. It is capable of filling out the most delicate lines and figures of forms in casting.

EXCERPTS AND REFERENCES.

Malleable Cast Iron (By H. E. Diller. JI. of the Am. Foundrymen's Assn.; Eng. News, Dec. 11, 1902).—"Malleable" can be made up to 60 000 lbs. per sq. in., though this is not advisable as the shock-resisting qualities are sacrificed. Yet as specifications become more severe the general quality of this class of castings will be improved until we get a more reliable article, and which can better resist the encroachments of the steel casting. The article discusses the methods of manufacture.

Manufacture and Properties of Nickel-Steel (By A. L. Colby. Proc. A. S. T. M., 1903; Eng. News, Aug. 20, 1903).—**Modulus of Elasticity.**—Young's modulus is practically the same for both tool steel containing 1.40% carbon and the mildest steel used in boilers. Their modulus of elasticity is in fact rarely found to be below 29,000,000 or above 31,000,000 and is generally taken at 29,500,000 or 30,000,000 in engineering calculations. The high nickel-steels, especially those containing 20% nickel or over, have a lower mod. of elas. than carbon-steel; but nickel-steels containing say 4% of nickel or less, such as are applicable for shafting, forgings, bridge construction, rails, etc., have the same mod. of elas. as carbon steels, viz., in the neighborhood of 29,000,000 lbs. per sq. in., many authorities claiming that this is true of even 5% nickel-steel. **Tensile Strength and Elastic Limit.**—Nickel-steel is chiefly distinguished from carbon-steel by its proportionately high elastic limit. If 3% nickel is alloyed with an open-hearth steel of 0.25% carbon, it produces a metal equal in tensile strength to a simple carbon-steel of 0.45% carbon, but having the advantageous ductility of the lower carbon-steel. On low carbon-steels not annealed, the addition of each 1% of nickel up to 5% causes approx., an increase of 5000 lbs. per sq. in. in the elastic limit, and 4000 lbs. in the ultimate or

tensile strength. The influence of nickel on the elastic limit and ultimate strength increases with the percentage of carbon present; high carbon nickel-steels showing a greater gain than low carbon nickel steels. **Other Properties Discussed.**—Effect of compression; rigidity; cold and quench bending tests; hardness; resistance to torsion; resistance to wear or abrasion; expansion; effect of punching and shearing; segregation.

Notes on the Metallurgy of Steel (By Bradley Stoughton. Trans. A. S. C. E., Vol. LIV, Part E).—See pages 398 to 406 of Transactions for 112 references to this subject.

Vanadium Steel Alloys (By J. Kent Smith. Soc. of Chemical Industry, Liverpool; Eng. News, May 24, 1906).—The vanadium steel industry is altogether an English industry, 80% of the production being used for the construction of motor cars and omnibuses. The chrome-vanadium steels containing 10 to 20% vanadium show the most remarkable properties, the highest test yet obtained, after special treatment, being a maximum breaking strength of 103 tons per sq. in. The nickel-vanadium steels are also of great strength, but show a lower resistance to dynamic and torsional tests.

Manganese Bronze (By C. R. Spare. Proc. A. S. T. M., Vol. XIII, 1906).—Properties of, with discussions.

Vanadium Structural Steel (By G. L. Norris. Eng. Rec., June 4, 1910).—Table of results of tests of angles made from three different heats of chrome-vanadium steel. "The best chrome-vanadium steels for rolled shapes have from 0.18 to 0.25% carbon, 0.25 to 0.40% manganese, 0.4 to 0.6% chrome, and 0.15 to 0.20% vanadium."

22.—BUILDING STONES AND CEMENTS.

(FOR WEIGHTS AND SPECIFIC GRAVITIES, SEE SECTION 27.)

This class of materials comprises all the non-metallic minerals of construction, including (I) Natural stones, (II) Cements, and (III) Artificial stones:

I. NATURAL BUILDING STONES.

These may be classified in three divisions, as follows:

- A. Crystalline siliceous rocks, or those of the igneous types containing much silica, as granites and sienites.
- B. Calcareous rocks, or those consisting mainly of lime, as limestones and marbles.
- C. Fragmentary rocks, as sandstones and slates.

A. Crystalline Siliceous Rocks.

Granite.—Granite is an igneous rock of granular and acid composition and, contrary to former belief, is now supposed to be forming today, from fusion, deep in the earth's crust. It is composed mainly of orthoclase, quartz, mica and usually feldspar, the following chemical analysis being typical: Silica (70), alumina (15), iron oxides (4), sodium oxide (4), potassium oxide (4), lime (2), magnesia (1).

Depending upon the material present in quantity, with quartz, of muscovite, hornblende or augite, we have respectively,

Muscovite granite. (Muscovite is a kind of mica.)

Hornblende granite,

Augite granite.

If the granite loses its quartz it grades into *Sienite*.

If potash feldspar is largely replaced by lime-soda feldspar it further grades into *Diorite*.

Granite is one of the most useful of building stones, but it is hard to work and cracks when subjected to great heat as evidenced by the Boston fire of 1871 on the Boston post office building, and by the recent Baltimore fire.

Basalt.—This term is applied to rocks of basaltic lava origin, comprising the so-called trap and the common greenstone. The basalts are very hard, heavy, and durable as building stone, the principal objection to their general use being the difficulty of working them,—quarrying and cutting. Basalt blocks are used principally as paving stone, resisting wear and tear to a remarkable degree.

Trap.—This includes a very wide range of extremely hard, crystalline rocks, and is sometimes applied outside the range of basalt. They are fine grained and usually dark-green in color. Broken trap rock makes an excellent base for concrete.

Greenstone.—When trap is altered by the presence of hornblende, chlorite, epidote, etc., it merges into greenstone, the green color being imparted by the hornblende.

B. Calcareous Rocks.

Limestone.—Pure limestone is carbonate of lime (CaCO_3), but there is sometimes present also carbonate of magnesia (MgCO_3) and certain so-called impurities, as alumina, silica, iron, etc. Carbonate of lime (CaO , CO_2) is a compound of lime (CaO) and carbonic acid (CO_2), the lime being an oxide of calcium,—an alkaline earth of specific gravity 3.18. Limestone and chalk are examples of carbonate of lime in the amorphous condition, while marble, aragonite and Iceland spar are varieties in the crystalline form.

of lime is abundantly present in both the organic and inorganic, the great beds of limestone being thus provided with their sources in their formation. The following are important: Formed of the fossil remains of the crinoid species of which is indicated by fragments of the coral stems. These are found in Indiana, Iowa and Kansas.

Composed of cemented fragments of shells and corals found on the sea on the coast of Florida.

A siliceous rock composed mainly of sea shells of the order Bivalvia and extensively on the coast of England and seems to be a limestone; not used as a building stone.

A limestone containing carbonate of lime (CaCO_3) and carbonate of magnesia (MgCO_3) in large proportions. It may be either crystalline (massive). The massive varieties containing iron pyrites. Dolomite is found in Vermont, Rhode Island, New Jersey, Missouri.

A limestone containing carbonate of lime (CaCO_3), carbonate of magnesia (MgCO_3), silicon dioxide (SiO_2) and alumina, having the property of hardening under water after it has been burned.

A mixture of calcium carbonate (45%) and clay, with perhaps some siliceous matter, as a building stone. Occurs in New Jersey, Kentucky, Virginia and the Carolinas.

A limestone deposit formed at the mouths of springs and

It may be considered as a high grade limestone, crystalline and capable of being polished. Those composed wholly of lime are white, while the various colorings in most of the marble are the presence of foreign matter. Most of our marble is obtained in this country, although it is obtained in many other states as Massachusetts, Tennessee, Maryland, Georgia, Pennsylvania, Arizona,

Foreign marbles imported to this country are the following:

White and gold, Carrara, Landscape, Nero antico.

Black, Grotto, Griotte.

White, Parian, Pentellic, Rosso antico.

Indian marble.

C. Fragmentary Rocks.

Sandstone may be called a "sand conglomerate," formed of sand grains cemented together. As a building stone the cementing material is quite hard, the whole mixture having been subjected to great pressure.

Sandstones when thoroughly dried will absorb about 20% weight of water; and in cold countries where buildings are exposed to the action of the frost it is best to present the foliated surface to the weather, in order to prevent flaking or frost chipping.

When quarried, usually lying *in situ* in layers of greater or less thickness. A channelling machine is used in cutting out the thickness being determined by the strata.

One, obtained from Berea, Ohio, is a gritty stone well adapted for general masonry construction. It is a grayish stone.

Another, quarried in New York (Medina) is largely used for foundations. It is reddish and argillaceous.

One (New York) sandstone is very hard and durable (sometimes called a reddish yellow stone, found in New York, Virginia, and Michigan).

Another (New York) sandstone is a Triassic brownstone, and a very important one.

Another sandstone is also Triassic.

Another sandstone composed mainly of quartz sand with siliceous cementation is the best. If metamorphosed into quartzite it is harder and more durable.

The best test of a sandstone is to expose it to the action of frost as in actual construction. This is the case with all the foregoing, which have been well tried and tested practically. An artificial freezing is sometimes applied to specimens from new quarries, which tests their power of resisting frost action. It consists in boiling the specimen 10 or 15 times in a strong solution of soda sulphate, exposing it to the action of the air for some hours after each boiling. The absorbed salt expands in crystallising, similar to frost action, flaking the specimen to a greater or less extent.

Flagstones are thinly bedded sandstones, the cleavage being parallel with the beds (usually). Bluestone is a variety found in Pennsylvania, New York and New Jersey.

Slate.—Slate is formed from shale under great pressure and heat. The cleavage planes may or may not be identical with the original shale foliation, but usually crosses them at different angles, and even at right angle to the bedding as in that at Slatington, Penn.

Roofing slate is a true slate, being a hard, compact rock apparently not affected by the weather. It may be laid on boarding or on terra cotta roofing, the lower edge of each third layer overlapping the upper edge of the first by an inch or more. Japanned malleable iron nails are used to avoid rust. Vermont and Pennsylvania furnish most of the slate quarried in the United States. It is also distributed throughout the South, North-west and California.

II. CEMENTS.

Materials with Cementing Properties may be mineral, vegetable or animal substances, either pure, mixed, or transmuted. The following substances have cementing qualities: *Mineral*.—Quartz, calcite and the iron ores; specifically, silica, lime, plaster of paris, sal ammoniac, sulphur, iron borings, brick dust, isinglass, clay, red lead, white lead, asphaltum, alum, copal, chalk, paraffin, gypsum, etc. *Vegetable*.—Gum, resin, wax and vegetable albumen; specifically, balsam, india rubber, rosin, starch, rice flour, wheat flour, mastic, etc. *Animal*.—Albumen, gelatin and glycerin; specifically, white of egg, lac, shellac, skim milk, cheese, beeswax, stearin, dextrin, etc. Gelatin is obtained by boiling animal substances as skins, hoofs, etc., in water.

The Solvents most common in the mixing of cements are water, alcohol, naphtha, vinegar, turpentine, linseed oil, benzine, petroleum, glycerin, ammonia, etc.

In the present discussion, cements are classed 'under Miscellaneous Cements, and (Builders) Cements.

MISCELLANEOUS CEMENTS.

Boiler cement.—To stop cracks and leaks in boilers and stoves. Dry powdered clay (6 parts), iron filings (1 part); mix to a paste with pure boiled linseed oil.

Coppersmith's cement.—To mend leaky joints in copper boilers. Bullocks blood thickened with quicklime; use immediately.

Fireproof cement.—To mend stone. Fine river sand (20), litharge (2), quicklime (1); mix to a thin paste with linseed oil.

Flour cement.—For general paste. To $\frac{1}{2}$ pint water add 1 tablespoonful wheat flour slowly, stirring rapidly; heat until it boils, stirring. Adding a little powdered alum to the water strengthens the paste; a little brown sugar and corrosive sublimate will preserve it from turning mouldy.

Gas Fitters' cement.—Resin (4 $\frac{1}{2}$), beeswax (1); melt, and stir in Venetian red (3); pour into iron- or oiled paper molds.

Iron cement.—For closing joints of iron pipes. Mix cast-iron borings or turnings (80) with sal-ammoniac (2), and flowers of sulphur (1). In using, add enough water to moisten; stir, and ram into joints. The sulphur is sometimes omitted.

Glue cement.—Glue (1), melted with water (least possible), and mixed with black resin (1) and red ochre ($\frac{1}{2}$).

Steam-Pipe cement.—Grind good linseed oil varnish with equal weights of white lead, manganese oxide, and pipeclay,

Keene's Marble cement.—For stucco work; will not stand weather. Baked gypsum or plaster of paris steeped in a saturated solution of alum and then recalcined and reduced to powder. To use, mix with water the same as plaster of paris.

For a complete list of cements and their preparation see *The Scientific American Cyclopaedia of Receipts, Notes and Queries*; also *Coolies' Cyclopaedia of Practical Receipts*.

(BUILDERS) CEMENTS.

Calcium (Ca) is a light-yellow metal whose specific gravity is 1.58, and which oxidizes at ordinary temperatures, hence it does not occur pure in nature, but is found abundantly as a component of calcite (CaCO_3), gypsum, dolomite, selenite, aragonite. Calcite or carbonate of lime is the principal constituent of limestone, marble and chalk. Calcium as a base plays a most important part in the limes, mortars and cements used in construction.

Lime (CaO), as its symbol implies, is an oxide of calcium, and may be obtained by placing calcium in contact with water, whence the latter is decomposed, forming lime and hydrogen gas (which latter escapes). Lime is a white, alkaline powder, of specific gravity 3.16. It may be obtained also by heating pure carbonate of lime or calcite ($\text{CaCO}_3 = \text{CaO} + \text{CO}_2$), whence the carbonic acid (CO_2) is driven off, leaving the lime. This is a pure lime and not the more or less impure, commercial article known to the engineer.

Common Lime is a more or less impure lime obtained by calcinating common limestone, composed mainly of CaCO_3 , in kilns or furnaces, thereby driving off the carbonic acid and organic impurities. Its purity is dependent mainly upon the mineral purity of the carbonate which is burned. **Quicklime** or burned lime (CaO + impurities) is the name given to it as it comes from the kilns. In this state it is white and has a specific gravity of 3.16. **Slacked lime** is quicklime which has been slacked by exposure to the air, whence the term "air slacked" in contradistinction to "water slacked." In the former case it absorbs carbonic acid and moisture from the air. Water slacked or simply common slacked lime is a calcium hydroxide (CaH_2O_2). Its specific gravity is 2.1 or about two-thirds that of quicklime, showing that slacking increases its bulk about one-half. "Fat lime" is obtained from limestone containing 5 per cent or less of impurities, and when these latter amount to 6 per cent the lime is poor.

Common Lime Mortar.—This is composed of common lime mixed with the required amount of sand, and freshly slacked to a smooth paste. The proportions of the mixture of lime, water and sand vary according to the quality of the lime and the class of work for which it is intended. An average proportion for brickwork is, by bulk, 1 of lime, 2 to 3 of sand. It will not set under water and is used only where in contact with air it can set slowly by absorbing carbonic acid (and some moisture). Lime mortar may contain any proportion of sand or even no sand.

For a fat lime and a good quality of cement the adhesive properties of the resulting mortar, after being set, are about as follows for various mixtures, calling that of pure lime paste unity:

Lime.	Sand.	Cohesion.
1	: 0	1.00
1	: 0.5	.905
1	: 1.	.82
1	: 1.5	.745
1	: 2	.68
1	: 2.5	.625
1	: 3	.58
1	: 3.5	.545
1	: 4	.52

Lime Plaster.—This consists approximately of 1 part quicklime, 2 parts sand, and to each 100 lbs. of the resulting mortar about $\frac{1}{4}$ bushel of cow-hair or other fine fibre is sometimes added to give it coherent strength. It is applied on wooden or metal laths. Many patent plasters are manufactured in slabs at the factories and shipped ready to be put in place. They are often compounds of gypsum.

Plaster of Paris.—When gypsum, a hydrated sulphate of lime ($\text{CaSO}_4 + 2\text{H}_2\text{O}$), is heated sufficiently, part of its water of crystallization is driven off, leaving the resulting composition (CaSO_4), called plaster of paris. This is one of the simplest of the mineral cements, and in addition to its value in the arts it is used for cementing slabs of marble in building construction. This consists in simply mixing the plaster of paris to a creamy paste and applying it. Its setting consists in taking on water, again crystallizing into the hydrate, gypsum. Plaster of paris is a useful constituent in many of the delicate cements. Its strength may be increased by mixing with it a solution of thin glue, albumen (white of egg), or vegetable gum. Many architectural ornaments are made of plaster of paris mixed with about an equal amount of paper pulp and a solution of size.

Hydraulic Lime.—As common lime is made by burning common limestone, so is hydraulic lime obtained in a similar way from hydraulic limestone, which contains a large amount of silica and alumina. In burning, these latter combine with part of the lime, forming lime silicates and aluminates, the other portion of the lime remaining free. The silicates and aluminates possess the power of hardening under water. It is used in high-class masonry construction in Europe, being replaced by cements in the United States.

Hydraulic Cement.—These cements are capable of hardening under water—containing a large amount, 25 to 50 per cent., of silica and alumina. They may be classed as natural, Portland (semi-natural), and slag (artificial or puzzolanic) cements.

Natural Cement is obtained by simply burning the natural hydraulic limestone at a low temperature, and grinding the clinker very fine. It is manufactured in Ulster County, N. Y.; Louisville, Ky.; Cumberland, Md.; Utica, Ill., and Milwaukee, Wis. The limestone contains much clay, which supplies the required silica and alumina. The product as shipped is composed, approximately, of lime (42 parts), silica (28), alumina (10), iron oxide, magnesia and impurities (20). This cement is usually called Roman cement in Europe, and *Rosendale* cement in the U. S. It is cheaper than Portland cement, gains strength more slowly, and sets more quickly.

Portland Cement.—Good Portland cement contains the usual hydraulic cement ingredients about as follows, namely, lime (62), silica (23), alumina (8), and other impurities including iron oxide, magnesia, sulphuric acid (7). It is prepared by selecting such natural materials that when mixed, ground, and calcined, the product will be the required compound as above. Thus, the proper silicates and aluminates of lime are obtained from a mixture of argillaceous limestones of different chemical composition; from relatively pure limestone and clay or chalk and clay; and from marl and clay. The resulting clinker is then ground to a powder. Sand-ground cement, as its name indicates, is a mixture of sand and Portland cement ground together. It increases the bulk of the "cement" considerably without reducing its strength, provided the ratio of sand to cement is not greater than 1 to 1, and the grinding is done properly, and with a good quality of sharp, siliceous sand. Portland cement is stronger than *Rosendale*, sets more slowly, but acquires its strength more rapidly.

Slag Cement.—This is made by grinding furnace slag with lime, the slag containing the other necessary ingredients—silica and alumina (also a small percentage of impurities). It is not employed to any great extent in the United States.

Bitumen.—Bitumen is a mineral pitch comprising the various class of substances known as asphalt, maltha, petroleum, naphtha, natural gas, etc. Bitumen is decomposed vegetable matter comprising mainly carbon and hydrogen, but containing also oxygen, sulphur and nitrogen in small proportions. Bituminous substances are found associated with the carboniferous rocks in pre-volcanic regions. Thus we have bituminous coal, -limestone, -sandstone, -shale, etc.

Asphalt.—This is one of the principal bitumens and is supposed to have been formed by the hardening of its allied liquid substances, maltha (mineral tar) and petroleum. Pitch Lake is a lake of asphalt on the island of Trinidad, and is controlled by the Trinidad Asphalt Co. of Philadelphia. Its product is of the finest quality, and supply apparently inexhaustible. Asphalt is a natural cement; its composition is practically unalterable.

when exposed to the natural elements; and it is quite plastic and practically water-proof. Thus, it forms an excellent road, pavement and roofing material, and as a coating preservative for water pipes it is unexcelled. Asphalt cement is simply the refined asphalt tempered generally with the residue from petroleum oil. Asphalt mastic is prepared by mixing asphalt cement with sand and perhaps crushed limestone, or by mixing maltha, the poorer quality of bitumen, with natural rock asphalt. The mixture is heated, and cooled in molds ready for use. Asphalt concrete consists of broken stone or gravel with asphalt mastic used as a binder.

Manufacture of Portland Cement.

Raw Materials.—The materials used in the manufacture of Portland cement are carbonate of lime and clay: occurring either more or less naturally mixed, as in the argillaceous limestones; or separate in natural beds, as the chalk deposits of England and the various clay deposits common in many countries. In England, chalk is the principal form of carbonate of lime employed, and this is mechanically mixed with estuary mud. In Germany, the chief material is "mergel" (marl), a limestone rock of greater or less hardness, containing clay; also "weisenkalk," a pure soft marl composed mainly of carbonate of lime. In the United States the marls similar to those of Germany are found in Ohio, Indiana, Michigan and New York, and, mixed with clay, are largely used in the manufacture of Portland cement; but most of our cement is made from certain limestones containing sufficient clay and nearly free from magnesia, and found in certain localities, as Phillipsburg, N. J., and Lehigh Co., Penn.

The three distinct operations in the manufacture of Portland cement are (1) Pulverizing and mixing the raw materials, (2) Calcination or burning, (3) Grinding the clinker. These are discussed as follows:

Pulverizing and Mixing.—There are two processes in use for mixing the raw materials preparatory to calcination. These are known as the "wet" process and the "dry" process, each naturally adapted to the class of materials to be mixed.

Wet Process.—This process is used for such materials as chalk, soft marl and clay, which, by the admixture of a large quantity of water in a "wash mill," can be reduced to a homogeneous creamy condition of "slip" or "slurry." The most recent practice in the United States is to grind the mixture in a liquid state, run it into tanks where it is kept continually stirred, and thence to the rotary tubular furnaces where it is calcined.

Dry Process.—This process is particularly adapted to the treatment of argillaceous limestones or limestones containing sufficient clay so that very little mechanical mixing is necessary; notably the limestones of Phillipsburg, N. J., Lehigh Co., Penn., and of some localities in the West. Such material is run into a "grinding machine" where it is ground to a greater or less degree of fineness, depending upon the relative admixture of carbonate of lime and clay; i.e., if they occur intimately mixed in the same rock in the right proportion, very little grinding is required. The process becomes very expensive, however, when an almost pure limestone rock and a clayey shale form the ingredients to be mixed, in which case they must first be crushed to the size of small pebbles, then mixed and ground to an impalpable powder to produce an intimate blending.

Calcination.—After pulverizing and mixing, the material is conducted to the rotary tubular furnace, where it is burned at a temperature of about 1600° F. Such a furnace consists of a steel tube usually from 60 to 100 ft. long, and 6 to 10 ft. in diameter, and lined with fire brick. It is arranged to rotate on rollers and is placed on a grade of about 5%. The raw mixture to be calcined is introduced at the higher end of the tubular furnace and, as the latter revolves, the heated material forms into small balls which slowly gravitate to the lower end, fall into a conveyer, and are carried to the clinker storage-room. The degree of burning is one of the most important considerations in cement manufacture.

Grinding the Clinker.—After calcination, the resulting clinker passes to the "ball mills" where it is broken up into sand, with a small proportion of dust. It then goes to the "pulverizer," where it is reduced to the required fineness of powder—cement.

Cement Testing.

Requisites of a Cement.—The principal requisites of a cement are that when combined with other materials of construction it shall possess the necessary resistance to disintegration, that is, (1) *strength* to resist safely the loads which may come upon it, and (2) *endurance* to withstand safely the continuous or repeated stresses to which it may be subjected, with the element "time" included. Certain factors affecting these qualities in a cement will now be considered.

Chemical Composition is one of the most important factors entering into both the strength and endurance of cement; hence, the raw materials should be selected in the proper proportions to give the required chemical mix in the finished product. The elements calcium, silicon, aluminum, carbon (and hydrogen) all unite with oxygen, forming oxides, the exact chemical composition being very complex, and varying greatly with different cements. Any foreign matter thus becomes an adulterant, tending to prevent "set" or hardening of the cement.

Set or Hardening of cement takes place when water is introduced into the anhydrous cement powder. It then becomes a hydrated compound in the form of an artificial stone. In Trans. A. S. C. E., Vol. LIV, Part F, pp. 48-52, Mr. R. L. Humphrey says: "This hydration or crystallization begins with the addition of water, and it is doubtful whether it ever ceases.

Upon the addition of water, it begins immediately to hydrate in the form of fine needle-like crystals, and it is the intermeshing of these crystals that produces the hardening. They can be seen forming under a microscope immediately upon the addition of water to cement. The action is analogous to the formation of crystals from a saturated salt solution. If water is added to a cement that has commenced to set, and it is again mixed, the crystals already formed will be broken up, and the mass weakened by this retempering. Successive repetitions will gradually destroy all bond, and the cement having set or crystallized, the mass will become like so much inert sand." The phenomenon of hardening, then, "is purely a chemical one and is the result of the mechanical intermeshing of the crystals of silicate of lime, etc., which are formed by the hydration of the cement powder."

It will thus be seen, from the above, that cement, cement mortar, and concrete should be placed in the work immediately after mixing, and should not subsequently be disturbed.

Rate of Setting or time of setting is an important feature in construction work. It is necessary that the cement should not be so "quick-setting" as to prevent proper manipulation of the mix and placing it in the structure, nor so "slow-setting" as to require extra time to set, thereby retarding the work. The term "set" is here used in the sense of "initial set" or that point of crystallization where any disturbance or displacement of the material would effectually weaken it. Both "initial set" and "final set" or "hard set" are indefinite terms because crystallization or hardening is a continuous process which goes on indefinitely. Cements which do not set in two hours are considered slow-setting. On the other hand, 10 to 30 minutes is usually allowed any cement for manipulation and placing, before initial set should appear. The rate of setting of cement may be increased by the addition of lime, or plaster of paris or gypsum, but the resultant strength is thereby decreased.

Fineness is absolutely necessary to the thorough crystallization and consequent hardening, previously described. If the grains are coarse the crystals and their intermeshing will be imperfect, which will also be the case if the cement powder does not contain the proper mix of the raw materials, and the right degree of calcination. An ideal cement is one in which the clinker has been pulverized to a "flour" or impalpable powder, thoroughly anhydrous, and containing elements in such proportion that when water is added the hydrated compound will form into innumerable perfect crystals, with no free matter to obstruct their formation. Of course this condition can never be realized because (1) the grinding or pulverizing is never carried to such an extreme degree, and (2) all cements contain more or less free matter, as excess of lime, magnesia, iron, etc. These two classes of imperfections affect the strength of the cement, and the second class also affects its "soundness" and consequently its endurance.

Soundness is a negative term used to express the property which a cement has of *not* unduly expanding, contracting, checking or cracking during setting, hardening or crystallization. Such deformations are due to "active" impurities in the cement, such as free magnesia, lime, sulphur trioxide, etc., which produce internal stresses and thereby impair both its strength and durability. The class of impurities above mentioned should not be confused with certain "inactive" or inert impurities or adulterations which affect only the strength of the cement and not its endurance.

Inactive Adulterants are present to a greater or less extent in nearly all cement, the effect being simply to reduce its strength and commercial value. Other inert adulterants, as sand, in sand-cement mortar, and sand, broken stone, gravel, etc., in concrete, are added to or mixed with cement purely on the grounds of economy, in order to increase the bulk of the cementing material, allowing its strength to be impaired to a point consistent with necessary safety.

Method of Testing Cement.—The following is a digest of the standard method of testing cements, submitted as a progress report by a Committee of the Am. Soc. of Civil Engineers in 1903 and 1904, and adopted by the Am. Soc. for Testing Materials in 1904:

Selection of Sample.—Generally, one barrel in every ten to be sampled, the sample to be a fair average of contents of package; it shall be passed through a sieve having 20 meshes per lin. in. to remove lumps before testing. In obtaining sample from barrels or bags, an auger or a sampling iron should be used, reaching from side to center.

A chemical analysis, if required, may be made in accordance with the method outlined in the Journal of the Society of Chemical Industry, published Jan. 15, 1902. The determination of the principal constituents of cement—silica, alumina, iron oxide and lime—is not conclusive as an indication of quality.

Specific Gravity.—This is most conveniently made with Le Chatelier's apparatus, which consists of a flask (D), Fig. 1, of 120 cu. cm. (7.32 cu. ins.) capacity, the neck of which is about 20 cm. (7.87 ins.) long. In the middle of this neck is a bulb (C), above and below which are two marks (F) and (E). The volume between these marks is 20 cu. cm. (1.22 cu. ins.). The neck has a dia. of about 9 mm. (0.35 in.), and is graduated to tenths of cu. centimeters above the mark (F). Benzine (62° Baumé naphtha), or kerosene free from water, should be used in making the determination.

The specific gravity can be determined in two ways: 1st, the flask is filled with either of these liquids to the lower mark (E), and 64 gr. (2.25 oz.) of powder, previously dried at 100° C. (212° F.) and cooled to the temp. of the liquid, is gradually introduced through the funnel (B) [the stem of which extends into the flask to the top of the bulb (C)], until the upper mark (F) is reached. The difference in weight between the cement remaining and the original quantity (64 gr.) is the weight which has displaced 20 cu. cm. 2nd, the whole quantity of powder is introduced, and the level of the liquid rises to some division of the graduated neck. This reading plus 20 cu. cm. is the volume displaced by 64 gr. of powder.

The specific gravity is then obtained by the formula: Specific gravity = weight of cement ÷ displaced volume.

The flask, during the operation, is kept immersed in water in a jar (A), in order to avoid variations in the temperature of the liquid. Results from different trials should agree within 0.01. The apparatus is conveniently cleaned by inverting the flask over a glass jar, and shaking it vertically until the liquid starts to flow freely, repeating the operation several times.

More accurate determinations may be made with the picnometer.

Fineness.—The fineness is determined by measuring the residue retained on certain sieves, those known as No. 100 and No. 200 being recommended for this purpose. The sieves should be circular, about 20 cm. (7.87 ins.) in dia., 6 cm. (2.36 ins.) high, and provided with a pan 5 cm. (1.97 ins.) deep, and a cover.

Fig. 1.

The wire cloth should be *woven* from brass wire having a dia. of 0.0045 in. for No. 100 sieve, and 0.0024 in. for No. 200 sieve. It should be mounted on the frames without distortion; the mesh should be regular in spacing and be within the limits: 96 to 100 meshes per lin. in. for No. 100, and 188 to 200 for No. 200. For the test, 50 to 100 grams (1.76 to 3.52 oz.) dried at a temperature of 212° F. prior to sieving, should be used.

The coarsely screened (and dried) sample is weighed and placed on the No. 200 sieve, which, with pan and cover attached is held in one hand in a slightly inclined position, and moved forward and backward, at the same time striking the side gently with the palm of the other hand, at the rate of about 200 strokes per min., and continued until not more than $\frac{1}{8}$ of 1% passes through after 1 minute of continuous sieving. The residue is weighed, then placed on the No. 100 sieve and the operation repeated. The results should be reported to the nearest $\frac{1}{8}$ of 1%. The work may be expedited by placing in the sieve a small quantity of large shot.

Normal Consistency.—The use of the proper percentage of water in making the pastes* from which pats, tests of setting and briquettes are made, is exceedingly important, affecting the results vitally. No method is entirely satisfactory, but the following is recommended:

VICAT NEEDLE TEST.

The apparatus used is known as the Vicat needle, which consists of a frame (K), Fig. 2, bearing a movable rod (L), with a cap (A) at one end, and at the other the cylinder (B), 1 cm. (0.39 in.) in dia.; the cap, rod and cylinder weighing 300 gr. (10.58 oz.). The rod, which can be held

Fig. 2.

in any desired position by a screw (F), carries an indicator, which moves over a scale (graduated to centimeters) attached to the frame (K). The paste is held by a conical, hard-rubber ring (I), 7 cm. (2.76 ins.) in dia. at the base, 4 cm. (1.57 ins.) high, resting on a glass plate (J), about 10 cm. (3.94 ins.) square.

In making the determination, the same quantity of cement as will subsequently be used for each batch in making the briquettes (but not less than 500 grains) is kneaded into a paste, as described under "Mixing," and quickly formed into a ball with the hands, completing the operation by tossing it six times from one hand to the other, maintained 6 ins. apart; the ball is then pressed into the rubber ring through the larger opening, smoothed off, and placed (on its large end) on a glass plate and the smaller end smoothed off with a trowel; the paste, confined in the ring, resting on the plate, is placed under the rod bearing the cylinder, which is brought in contact with the surface and quickly released.

The paste is of normal consistency when the cylinder penetrates to a point in the mass 10 mm. (1.39 in.) below the top of the ring. Great care must be taken to fill the ring exactly to the top.

The trial pastes are made with varying percentages of water until the correct consistency is obtained.

The Committee has recommended, as normal, a paste the consistency of which is rather wet, because it believes that variations in the amount of compression to which the briquette is subjected in moulding are likely to be less with such a paste.

* The term "paste" is here used to designate a mixture of cement and water, and the word "mortar" a mixture of cement, sand and water.

Having determined in this manner the proper percentage of water required to produce a paste of normal consistency, the proper percentage for the mortars may be obtained from an empirical formula, which the Committee hopes to devise; but temporarily the following Table* may be used:

PERCENTAGE OF WATER FOR STANDARD SAND MORTARS.

Neat.	One Cement, Three Standard Ottawa Sand.	Neat.	One Cement, Three Standard Ottawa Sand.	Neat.	One Cement, Three Standard Ottawa Sand.
15	8.0	23	9.3	31	10.7
16	8.2	24	9.5	32	10.8
17	8.3	25	9.7	33	11.0
18	8.5	26	9.8	34	11.2
19	8.7	27	10.0	35	11.5
20	8.8	28	10.2	36	11.5
21	9.0	29	10.3	37	11.7
22	9.2	30	10.5	38	11.8

	1 to 1	1 to 2	1 to 3	1 to 4	1 to 5
Cement.....	500	333	250	200	167
Sand.....	500	666	750	800	833

Time of Setting.—The object of this test is to determine the time which has elapsed from the moment water is added until the paste ceases to be fluid and plastic (called the "initial set"), and also the time required for it to acquire a certain degree of hardness (called the "final" or "hard set"). The former of these is the most important, since, with the commencement of setting, the process of crystallization or hardening is said to begin. As a disturbance of this process may produce a loss of strength, it is desirable to complete the operation of mixing and moulding, or incorporating the mortar into the work, before the cement begins to set.

It is usual to measure arbitrarily the beginning and end of the setting by the penetration of weighted wires of given diameters. For this purpose the Vicat needle, already described, should be used. In making the test, a paste of normal consistency is moulded and placed under the rod (L), Fig. 2, as described under "Normal Consistency;" this rod, bearing the cap (D) at one end and the needle (H), 1 mm. (0.039 in.) in dia., at the other, weighing 300 gr. (10.58 oz.). The needle is then carefully brought in contact with the surface of the paste and quickly released. The setting is said to have commenced when the needle ceases to pass a point 5 mm. (0.20 in.) above the upper surface of the glass plate, and is said to have terminated the moment the needle does not sink visibly into the mass.

The test pieces should be stored in moist air during the test; this is accomplished by placing them on a rack over water contained in a pan and covered with a damp cloth, the cloth to be kept away from them by means of a wire screen; or they may be stored in a moist box or closet. Care should be taken to keep the needle clean, as the collection of cement on the sides of the needle retards the penetration, while cement on the point reduces the area and tends to increase the penetration.

The determination of the time of setting is only approximate, being materially affected by the temperature of the mixing water, the temperature and humidity of the air during the test, the percentage of water used, and the amount of moulding the paste receives.

Standard Sand.—The Committee recognizes the grave objections to the standard quartz now generally used, especially on account of its high percentage of voids, the difficulty of compacting in the moulds, and its lack of uniformity. It recommends, for the present, the natural sand from Ottawa, Ill., screened to pass a sieve having 20 meshes per lin. in., and re-

* Prepared by the Committee on Standard Specifications for Cements as a temporary expedient.

tained on a sieve having 30 meshes per lin. in.; the wires to have diameters of 0.0165 and 0.0112 in., respectively, i.e., half the width of the opening in each case. Sand having passed the No. 20 sieve shall be considered standard when not more than 1% passes a No. 30 sieve after one minute continuous sifting of a 500-gram sample. The Sandusky Portland Cement Co., of Sandusky, O., has agreed to undertake the preparation of this sand, and to furnish it at a price only sufficient to cover the actual cost of preparation.

Form of Briquette.—While the form of the briquette recommended by a former Committee of the Society is not wholly satisfactory, this Committee is not prepared to suggest any change, other than rounding off the corners by curves of $\frac{1}{4}$ -in. radius, Fig. 3.

Moulds.—The moulds should be made of brass, bronze, or some equally non-corrodible material, having sufficient metal in the sides to prevent spreading during moulding. Gang moulds, as shown in Fig. 4, are preferred to single moulds, since the greater quantity of mortar that can be mixed for simultaneous moulding tends to produce greater uniformity in the results. They should be wiped out with an oily cloth before using.

Mixing.—All proportions should be stated by weight; the quantity of water to be used should be stated as a percentage of the dry material. The metric system is recommended because of the convenient relation of the gram and the cubic centimeter. The temperature of the room and the mixing water should be as near 70° F. as it is practicable to maintain it.

The sand and cement should be thoroughly mixed dry, and on some non-absorbing surface, preferably plate glass. If an absorbing surface is used it should previously be dampened. The quantity of material to be mixed at one time depends on the number of test pieces to be made; about 1000 gr. (35.28 oz.) makes a convenient quantity to be mixed, especially by hand methods. The material is weighed and placed on the mixing table, and a crater formed in the center, into which the proper percentage of clean water is poured; the material on the outer edge is turned into the crater by the aid of a trowel. As soon as the water has been absorbed, which should not require more than one minute, the operation is completed by vigorously kneading with the hands for an additional $1\frac{1}{2}$ minutes, the process being similar to that used in kneading dough. A sand-glass affords a convenient guide for the time of kneading. During the operation of mixing, the hands should be protected by gloves, preferably of rubber.

Moulding.—Having worked the paste or mortar to the proper consistency it is at once placed in the moulds by hand, being pressed in firmly with the fingers and smoothed off with a trowel without ramming. It should be heaped up on the upper surface of the mould, and, in smoothing off, the trowel should be drawn over the mould in such a manner as to exert a moderate pressure on the excess material. The mould should be turned over and the operation repeated. A check upon the uniformity of the mixing and moulding is afforded by weighing the briquettes just prior to immersion, or upon removal from the moist closet. Those varying in weight more than 3% from the average should be rejected.

Storage of the Test Pieces.—During the first 24 hours after moulding, the test pieces should be kept in moist air to prevent them from drying out. A moist closet or chamber is so easily devised that the use of the damp cloth should be abandoned if possible. Covering the test pieces with a damp cloth is objectionable, as commonly used, because the cloth may dry out unequally, and, in consequence, the test pieces are not all maintained under the same conditions. Where a moist closet is not available, a cloth may be used and kept uniformly wet by immersing the ends in water, and being kept from direct contact with the test pieces by means of a wire screen or some similar arrangement.

Fig. 3.

Fig. 4.

A moist closet consists of a soapstone or slate box, or a metal lined wooden box—the metal lining being covered with felt and this felt kept wet. The bottom of the box is so constructed as to hold water, and the sides are provided with cleats for holding glass shelves on which to place the briquettes. Care should be taken to keep the air in the closet uniformly moist.

After 24 hours in moist air, the test pieces for longer periods of time should be immersed in water maintained as near 70° F. as practicable; they may be stored in tanks or pans, which should be of non-corrodible material.

Tensile Strength.—The tests may be made on any standard machine. A solid metal clip, as shown in Fig. 5, is recommended. This clip is to be used without cushioning at the points of contact with the test specimen. The bearing at each point of contact should be $\frac{1}{2}$ in. wide, and the distance between the centers of contact on the same clip should be $1\frac{1}{2}$ ins.

Test pieces should be broken as soon as they are removed from the water. Care should be observed in centering the briquettes in the testing machine, as cross-stains, produced by improper centering, tend to lower the breaking strength. The load should not be applied too suddenly, as it may produce vibration, the shock from which often breaks the briquette before the ultimate strength is reached. Care must be taken that the clips and the sides of the briquette be clean and free from grains

Fig. 5.

of sand or dirt, which would prevent a good bearing. The load should be applied at the rate of 600 lbs. per minute. The average of the briquettes of each sample tested should be taken as the test, excluding any results which are manifestly faulty.

Constancy of Volume.—The object is to develop those qualities which tend to destroy the strength and durability of a cement. As it is highly essential to determine such qualities at once, tests of this character are for the most part made in a very short time, and are known, therefore, as *accelerated tests*. Failure is revealed by cracking, checking, swelling or disintegration, or all of these phenomena. A cement which remains perfectly sound is said to be of constant volume.

Tests for constancy of volume are divided into two classes: (1) normal tests, or those made in either air or water maintained at about 70° F., and (2) accelerated tests, or those made in air, steam or water at a temperature of 115° F. and upward. The test pieces should be allowed to remain 24 hours in moist air before immersion in water or steam, or preservation in air.

For these tests, pats, about $7\frac{1}{2}$ cm. (2.95 ins.) in dia., $1\frac{1}{2}$ cm. (0.49 in.) thick at the center, and tapering to a thin edge, should be made, upon a clean glass plate [about 10 cm. (3.94 ins.) square], from cement paste of normal consistency.

Normal Test.—A pat is immersed in water maintained as near 70° F. as possible for 28 days, and observed at intervals. A similar pat is maintained in air at ordinary temperature and observed at intervals.

Accelerated Test.—A pat is exposed in any convenient way in an atmosphere of steam, above boiling water, in a loosely closed vessel, for 3 hours.

To pass these tests satisfactorily, the pats should remain firm and hard, and show no signs of cracking, distortion or disintegration. Should the pat leave the plate, distortion may be detected best with a straight-edge applied to the surface which was in contact with the plate. In the present state of our knowledge it cannot be said that cement should necessarily be condemned simply for failure to pass the accelerated tests; nor can a cement be considered entirely satisfactory simply because it has passed these tests.

Specifications for Cement (A. S. T. M.).

The following specifications were adopted by the American Society for Testing Materials, Nov. 14, 1904:

General Conditions.—(1) All cement shall be inspected. (2) Cement may be inspected either at the place of manufacture or on the work. (3) In order to allow ample time for inspecting and testing, the cement should be stored in a suitable weather-tight building having the floor properly blocked or raised from the ground. (4) The cement shall be stored in such

a manner as to permit easy access for proper inspection and identification of each shipment. (5) Every facility shall be provided by the contractor and a period of at least twelve days allowed for the inspection and necessary tests. (6) Cement shall be delivered in suitable packages with the brand and name of manufacture plainly marked thereon. (7) A bag of cement shall contain 94 pounds of cement net. Each barrel of Portland cement shall contain 4 bags, and each barrel of natural cement shall contain 3 bags of the above net weight. (8) Cement failing to meet the 7-day requirements may be held awaiting the results of the 28-day tests before rejection. (9) All tests shall be made in accordance with the methods proposed by the Committee on Uniform Tests of Cement of the American Society of Civil Engineers, presented to the Society January 21, 1903, and amended January 20, 1904, with all subsequent amendments thereto. [See "Method of Testing Cement," page 407.]

(10) The acceptance or rejection shall be based on the following requirements:

(11) *Natural Cement.*—Definition.—This term shall be applied to the finely pulverized product resulting from the calcination of an argillaceous limestone at a temperature only sufficient to drive off the carbonic acid gas.

(12) *Specific Gravity.*—The specific gravity of the cement thoroughly dried at 100° C., shall not be less than 2.8.

(13) *Fineness.*—It shall leave by weight a residue of not more than 10% on the No. 100, and 30% on the No. 200 sieve.

(14) *Time of Setting.*—It shall develop initial set in not less than 10 minutes, and hard set in not less than 30 minutes nor more than 3 hours.

(15) *Tensile Strength.*—The minimum requirements for tensile strength for briquettes one inch in cross section shall be within the following limits, and shall show no retrogression in strength within the periods specified:*

Age.	Neat Cement.	Strength.
24 hours in moist air.....		50-100 lbs.
7 days (1 day in moist air, 6 days in water).....		100-200 "
28 days (1 day in moist air, 27 days in water).....		200-300 "
One Part Cement, Three Parts Standard Sand.		
7 days (1 day in moist air, 6 days in water).....		25-75 "
28 days (1 day in moist air, 27 days in water).....		75-150 "

(16) *Constancy of Volume.*—Pats of the neat cement about 3 ins. in diameter, $\frac{1}{4}$ -in. thick at center, tapering to a thin edge, shall be kept in moist air for a period of 24 hours. (a) A pat is then kept in air at normal temperature. (b) Another is kept in water maintained as near 70° F. as practicable.

(17) These pats are observed at intervals for at least 28 days, and, to satisfactorily pass the test, should remain firm and hard and show no signs of distortion, checking, cracking or disintegrating.

(18) *Portland Cement.*—Definition.—This term is applied to the finely pulverized product resulting from the calcination to incipient fusion of an intimate mixture of properly proportioned argillaceous and calcareous materials, and to which no addition greater than 3% has been made subsequent to calcination.

(19) *Specific Gravity.*—The specific gravity of the cement, thoroughly dried at 100° C., shall not be less than 3.10.

(20) *Fineness.*—It shall leave by weight a residue of not more than 8% on the No. 100, and not more than 25% on the No. 200 sieve.

(21) *Time of Setting.*—It shall develop initial set in not less than 30 minutes, but must develop hard set in not less than one hour nor more than ten hours.

* For example, the minimum requirement for the 24-hour neat cement test should be some specified value within the limits of 50 and 100 lbs., and so on for each period stated. [The consumer, when ordering, may fix the min. value.]

(22) *Tensile Strength*.—The minimum requirements for tensile strength for briquettes one inch square in section shall be within the following limits, and shall show no retrogression in strength within the periods specified:*

Age.	Neat Cement.	Strength.
24 hours in moist air.....		150-200 lbs.
7 days (1 day in moist air, 6 days in water).....		450-550 "
28 days (1 day in moist air, 27 days in water).....		550-650 "
One Part Cement, Three Parts Sand.		
7 days (1 day in moist air, 6 days in water).....		150-200 "
28 days (1 day in moist air, 27 days in water).....		200-300 "

(23) *Constancy of Volume*.—Pats of neat cement about 3 ins. in diameter, $\frac{3}{4}$ -in. thick at the center, and tapering to a thin edge, shall be kept in moist air for a period of 24 hours. (a) A pat is then kept in air at normal temperature and observed at intervals for at least 28 days. (b) Another pat is kept in water maintained as near 70° F. as practicable, and observed at intervals of at least 28 days. (c) A third pat is exposed in any convenient way in an atmosphere of steam, above boiling water, in a loosely closed vessel for five hours.

(24) These pats, to satisfactorily pass the requirements, shall remain firm and hard and show no signs of distortion, checking, cracking or disintegrating.

(25) *Sulphuric Acid and Magnesia*.—The cement shall not contain more than 1.75% of anhydrous sulphuric acid (SO_3), nor more than 4% of magnesia (MgO).

Specifications for Cement (Engrs. U. S. A.).

The following specifications† are from Professional Papers, No. 28, Corps of Engineers, U. S. A.

(a) *American Portland Cement*.—Shall be dry and free from lumps; the calcined product to contain at least 1.7 times as much lime, by weight, as of the materials which give the lime its hydraulic properties; and to be finely pulverized after said calcination, with subsequent additions or substitutions for regulating certain properties of technical importance not to exceed 2% of the calcined product.

The cement to be put up in strong, sound barrels, well lined with paper, or in stout cloth or canvas sacks; each package to be plainly labeled with name of brand and of manufacturer. Bidders will state the brand which they propose to furnish. The average weight per barrel shall not be less than 375 lbs. net. Four sacks shall contain one barrel of cement.

Tests may be made of the fineness, specific gravity, soundness, time of setting, and tensile strength of the cement.

(7) *Fineness*.—Ninety-two per cent of the cement must pass through a sieve made of No. 40 wire, Stubb's gauge, having 10,000 openings per square inch.

(8) *Specific Gravity*.—The specific gravity of the cement, as determined from a sample which has been carefully dried, shall be between 3.10 and 3.25.

(9) *Soundness*.—To test the soundness of the cement, at least two pats of neat cement, as taken from the package, mixed for five minutes with about 20 per cent of water by weight shall be made on glass, each pat about 3 inches in diameter and one-half inch thick at the center, tapering thence to a thin edge. The pats are to be kept under a wet cloth until finally set, when one is to be placed in fresh water for twenty-eight days. The second pat will be placed in water which will be raised to the boiling point for six

* For example, the minimum requirement for the 24-hour neat cement test should be some specified value within the limits of 150 and 200 lbs., and so on for each period stated. [The consumer, when ordering, may fix the minimum values.]

† A digest from the Report of Majors W. L. Marshall and S. S. Leach, and Capt. Spencer Crosby, Board of Engineer Officers, on testing Hydraulic Cements, with specifications for the several classes; Second Edition, with Corrections, 1902.

hours, then allowed to cool. Neither should show distortion or cracks. The boiling test may or may not reject at the option of the engineer officer in charge.

(10) *Time of Setting*.—The cement shall not acquire its initial set in less than forty-five minutes and must have acquired its final set in ten hours.

(The following paragraph will be substituted for the above in case a quick-setting cement is desired:

The cement shall not acquire its initial set in less than twenty nor more than thirty minutes, and must have acquired its final set in not less than forty-five minutes nor in more than two and one-half hours.)

The pats made to test the soundness may be used in determining the time of setting. The cement is considered to have acquired its initial set when the pat will bear, without being appreciably indented, a wire one-twelfth inch in diameter loaded to weigh one-fourth pound. The final set has been acquired when the pat will bear, without being appreciably indented, a wire one twenty-fourth inch in diameter loaded to weigh 1 pound.

(11) *Tensile Strength*.—Briquettes made of neat cement, after being kept in air for twenty-four hours under a wet cloth and the balance of the time in water, shall develop tensile strength per sq. in. as follows: 7 days, 450 lbs; 28 days, 540 lbs. Briquettes made of 1 part cement and 3 parts standard sand, by weight, shall develop tensile strength per sq. in. as follows: 7 days, 140 lbs; 28 days, 220 lbs. (In case quick-setting cement is desired, the following tensile strengths shall be substituted for the above: Neat briquettes: 7 days, 400 lbs.; 28 days, 480 lbs. Briquettes of 1 part cement to 3 parts standard sand: 7 days, 120 lbs.; 28 days, 180 lbs.)

The highest result from each set of briquettes made at any one time, is to be considered the governing test. Any cement not showing an increase of strength in the 28-day tests over the 7-day tests will be rejected.

(b) *Natural Cement*.—The average net weight per barrel shall not be less than 300 lbs. (West of the Allegheny Mountains this may be 265 lbs.)

(7) *Fineness*.—At least 80 per cent of the cement must pass through a sieve made of No. 40 wire, Stubb's gauge, having 10,000 openings per square inch.

(8) *Time of Setting*.—The cement shall not acquire its initial set in less than twenty minutes and must have acquired its final set in four hours.

(9) The time of setting is to be determined from a pat of neat cement mixed for five minutes with 30 per cent of water by weight and kept under a wet cloth until finally set. The cement is considered to have acquired its initial set when the pat will bear, without being appreciably indented, a wire one-twelfth inch in diameter loaded to weigh one-fourth pound. The final set has been acquired when the pat will bear, without being appreciably indented, a wire one twenty-fourth inch in diameter loaded to weigh 1 pound.

(10) *Tensile Strength*.—Briquettes made of neat cement shall develop the following tensile strengths per square inch, after having been kept in air for twenty-four hours under a wet cloth and the balance of the time in water: at the end of 7 days, 90 lbs.; 28 days, 200 lbs. Briquettes made of 1 part cement and 1 part standard sand, by weight, shall develop the following tensile strengths pr sq. in.: 7 days, 60 lbs.; 28 days, 150 lbs.

(c) *Puzzolan Cement*.—The average weight per barrel shall not be less than 330 lbs. net. Four sacks shall contain one barrel of cement.

(7) *Fineness*.—Ninety-seven per cent of the cement must pass through a sieve made of No. 40 wire, Stubb's gauge, having 10,000 openings per square inch.

(8) *Specific Gravity*.—The specific gravity of the cement, as determined from a sample which has been carefully dried, shall be between 2.7 and 2.8.

(9) *Soundness*.—To test the soundness of cement, pats of neat cement mixed for five minutes with 18 per cent. of water by weight shall be made on glass, each pat about 3 inches in diameter and one-half inch thick at the center, tapering thence to a thin edge. The pats are to be kept under wet cloths until finally set, when they are to be placed in fresh water. They should not show distortion or cracks at the end of twenty-eight days.

(10) *Time of Setting*.—The cement shall not acquire its initial set in less than forty-five minutes and shall acquire its final set in ten hours. The pats made to test the soundness may be used in determining the time of setting. The cement is considered to have acquired its initial set when the pat will bear, without being appreciably indented, a wire one-twelfth inch in diameter loaded to one-fourth pound weight. The final set has been acquired when the pat will bear, without being appreciably indented, a wire one twenty-fourth inch in diameter loaded to 1 pound weight.

(11) *Tensile Strength*.—Briquettes made of neat cement, after being kept in air under a wet cloth for twenty-four hours and the balance of the time in water, shall develop tensile strengths per square inch as follows: After 7 days, 350 lbs.; 28 days, 500 lbs. Briquettes made of 1 part cement and 3 parts standard sand, by weight, shall develop tensile strength per sq. in. as follows: 7 days, 140 lbs., 28 days, 220 lbs.

III. ARTIFICIAL BUILDING STONES.

The following classification, which includes brick, is convenient in the present discussion:

- (1) Brick, usually an argillaceous material, molded to the required form, and baked.
- (2) Concrete, consisting of a matrix of cement and sand, properly mixed with a stone aggregate, *in situ*.
- (3) Block stone, a hydraulic cement concrete specially treated and formed in moulds at the factory.

(1) Brick.

A good brick clay consists of a fairly pure hydrated silicate of alumina, but contains also more or less so-called impurities as iron, manganese, free silica (sand), potash, lime, etc. In making bricks the clay is well kneaded, molded, dried, and then burned in kilns.

Common brick is designated as "clinker," "hard" or "soft," denoting the degree of burning in the kiln. *Clinker* bricks have been overburned and usually have a blueish cast; they are partly vitrified, and brittle. *Hard* bricks are the best burned, red brick. *Soft* bricks are those which are under-burned, and are paler than the hard. In addition to the amount of burning, the color of brick is much affected by the quantity of iron or lime in the clay; the presence of iron peroxide produces a red brick while lime has a tendency to make it yellow. The common standard of brick in the United States is $8\frac{1}{2}'' \times 4'' \times 2\frac{1}{2}''$; in England, $8\frac{1}{2}'' \times 4\frac{1}{2}'' \times 2\frac{1}{2}''$.

Face brick is made from one of more specially selected clays, mixed if necessary to give the desired chemical properties and color. The bricks are pressed in the molding machine, hence the name "pressed brick." They are also sometimes re-pressed. The standard size in the United States is $8\frac{1}{2}'' \times 4'' \times 2\frac{1}{2}''$.

Glazed brick is a brick coated with enamel, a fusible salt. A common liquid glass for glazing is composed of silicic acid (23.2 per cent.), soda (5.9), potash (2.5), water (65.4). The glazing may be in various colors and consequently pretty patterns may be obtained. Glazed bricks are used in buildings and subways; they are hygienic as well as ornamental.

Vitrified brick.—Vitrification is obtained from the thorough burning of a highly siliceous clay or of a clay mixed with a large amount of siliceous sand.

Terra Cotta, meaning baked earth, is made of a specially graded clay or clays mixed with a certain amount of siliceous sand, if necessary, to secure the desired amount of vitrification. After molding and drying, the mixture is baked. The surface of terra cotta may also be glazed like that of the common glazed brick and tile.

Fire brick is used for the lining of furnaces, chimneys, etc. It is made from the natural fire-clay of which large beds are found in New Jersey and elsewhere. It is a high graded hydrated silicate of alumina, containing preferably not over 4 per cent. of impurities. The clay contains a large proportion of silica (sand), and sometimes more is added to insure its refractory quality. The manufacture is similar to that of common brick, but with the fire-clay the product is vitrified.

Paving brick is not so much vitrified as fire brick.

Sewer brick is ordinary, hard brick.

(2) Concrete (*En-masse*).

(SEE, ALSO, CONCRETE MASONRY, PAGE 439.)

*Concrete** is composed of a *matrix* possessing cementing properties thoroughly mixed and united with an *aggregate* or base composed of elements of hard, imperishable, mineral substances, the whole forming a compact, enduring mass. The matrix is the cement-sand-water mortar, while the aggregate is the crushed rock or gravel base.

Mixture.—The cement and sand are thoroughly mixed dry in the proper proportion, enough water being added subsequently to form a paste, wet sand. After this matrix has been carefully kneaded, the aggregate which has previously been washed of all dirt and other injurious matter is added, and the whole mass thoroughly mixed. It should be placed immediately and tamped, with the water just flushing the surface.

An ideal concrete is one in which the entire surface of every grain of sand is covered with the mortar paste, with the grains nearly touching each other but with no voids; and in which also all interstices of the aggregate are completely filled with the matrix, pressing firmly against every surface. An unduly large proportion of cement may make the mass unnecessarily strong and expensive, while too little cement will render it porous and possibly too weak. Where great strength is not essential a cheaper brand of cement may be used instead of the most expensive, perhaps used in a greater proportion, sufficient to fill all sand voids, thus rendering the mass non-porous at no greater cost. This is an essential consideration in localities where frosts are liable to work injuriously upon the mass of concrete if porous. As with cement, in regard to voids in the sand, so with the matrix regarding voids in the aggregate. An excess of matrix means excessive cost, while a deficiency gives a porous concrete. The latter is avoided by thorough tamping and proper flushing, and by varying the proportion if necessary.

Proportions.—The proportions, by bulk, in mixing concrete are usually based on 1 of cement, 2 to 3 of sand, and 4 to 7 of aggregate, depending upon the nature and class of the work as well as the quality and kind of materials available. Portland cement is the best, and costs more than the other brands. It is usually specified in first class work. In ordinary work it often gives better results than the cheaper brands, at no greater cost because it "goes further"; bearing in mind of course that if scantily used the matrix will be more or less porous. A greater proportion of sand can be used in the matrix if it is fine and siliceous, hence a little money spent on sand will sometimes save a much greater sum on cement. Lastly, much less matrix and consequently less cement is required if the aggregate is graded to different sizes, lessening the voids.

The voids in sand amount, generally, to about 33 or 34% of the gross bulk; in gravel, to about the same; in broken sandstone, to about 40 to 42%; in broken trap, to about 45 to 50%. Generally, the percentage of voids is greater in the freshly broken, hard, flint-like rocks, and less in the soft rock which leave the crusher with less-defined edges. With gravel, where the edges have worn away, the percentage of voids is the least, hence gravel is the most economical aggregate to use for concrete because less cement or mortar, is required. For the same reason, basalt or trap are the most expensive, although far superior for many purposes.

Economy in cement may be practiced by grading the size of materials as previously noted; thus, a coarse and a fine sand may be used together in forming the matrix, while the aggregate may consist of graded gravel or gravel and broken stone.

* Before hydraulic cement became recognized as an essential ingredient in concrete, lime of greater or less hydraulic properties was sometimes mixed with hydraulic cement or asphalt, etc. Thus,

<i>Kind of concrete.</i>		<i>Matrix.</i>	<i>Aggregate.</i>
Hydraulic cement c.	lime	Hydraulic cement mortar.	} Broken stone, crushed brick, slag cinders, pebbles, gravel, etc.
Asphalt cement "		Asphalt cement "	

"Concrete" is now universally recognized as hydraulic cement concrete.

Cement-Sand Mix.—To get the proper proportion of cement to sand in the matrix: Determine the percentage of voids in the sand by noting the quantity c of water required to "flush" to the level in a water-tight box filled with an s quantity of the sand to be used; then the proportion of cement to sand should be about $1.1 c : s$. It is to be noted that the amount of cement required is thus about 10% in excess of the voids in the sand, which is as it should be, as the sand grains will be coated with the cement and separated somewhat from each other. For example, using sand with 34% voids, the ratio of cement to sand would be about $1 : 2\frac{1}{2}$. In practice this ratio is sometimes increased to $1 : 2$, $1 : 1\frac{1}{2}$, or $1 : 1$, depending upon the character and importance of the work, and also upon the character and quality of the materials. A $1 : 2$ mix is generally considered good practice for a cement mortar in first class masonry work; while a $1 : 1$ mix makes an excellent wearing surface when used as a finishing coat for concrete walks.

Cement-Sand-Broken-stone Mix.—To get the proper proportion of matrix to aggregate: Determine the percentage of voids in the aggregate or broken stone by noting the quantity m of water required to "flush" to the level in a water-tight box filled with an a quantity of broken stone; then the proportion of matrix to aggregate should be about $1.1 m : a$. For example, with 45% voids in the aggregate, the ratio of mortar to broken stone should be about $1 : 2$.

Further, if we assume the sand voids at 34%, as above, the cement-sand-broken stone ratio would be about $1 : 2\frac{1}{2} : 5$. Note that the quantity of sand in the matrix, slightly increased, really determines the bulk of the matrix itself in estimating the above ratio. In practice, this ratio is sometimes increased to $1 : 2 : 4$ mix for first class building walls, piers and buttresses; to $1 : 1\frac{1}{2} : 3$ mix for columns and heavy beams of concrete-steel; and to $1 : 1 : 2$ mix for lighter reinforced members.

Size of Broken Stone.—The size to which the stone must be crushed or broken will be governed somewhat by the size of the concrete mass. For large bridge piers, stone which will pass through a $2\frac{1}{2}$ -in. ring in any way is often allowed. The most common specification, however, for such foundations stipulates the 2-in. ring. For certain classes of work both an upper and a lower limit are specified; as for instance, rock that will pass through a $2\frac{1}{2}$ -in. but not through a 1-in. ring, called the $2\frac{1}{2}$ "-1" grade; similarly, we may have a 2"- $1\frac{1}{2}$ " grade, a $1\frac{1}{2}$ "- $\frac{1}{2}$ " grade, etc. Much refinement in this respect is, however, unnecessarily expensive, excepting perhaps in building construction and notably in concrete-steel work. For the latter, sizes as small as the pea-grade size are used for reinforced floors.

(3) Block Stone.

By this is meant the commonly named "artificial stone" proper. It is manufactured usually at the factory and shipped to the site for erection. Among the most important kinds are the following:

Béton-Colonet.—This was invented by Coignet, a Frenchman, and consisted of Portland cement, siliceous hydraulic cement, and clean sharp sand, thoroughly mixed with a small quantity of water, and placed in molds to set, for use.

Sand bricks are manufactured from lime and sand mixed with water to the consistency of a mortar. This mortar is molded into bricks or blocks and then hardened by heating.

Portland stone is composed of a mixture of Portland cement with water and sand or gravel, placed in molds and thoroughly rammed for setting. It is made plain and also ornamental.

McMurtrie stone is made of Portland cement concrete to which is added a solution of castile soap and a solution of alum, forming compounds of alumina potash and certain acids, which tend to "set" the concrete quickly. It is not attacked by the weather.

Ransome stone.—The aggregate consists of broken granite, gravel or sand; the matrix, a silicate of soda and sand immersed in a hot solution of chloride of calcium. It makes a very good building stone.

Sorel stone.—The matrix consists of a solution of magnesium chloride added to the oxide of magnesium. The aggregate is a finely crushed or powdered stone of good quality. It is extremely hard and is used for imitation marble, emery wheels, etc.

EXCERPTS AND REFERENCES.

Lutes and Cements Useful to Engineers (By S. S. Sadtler. Paper, Phila. Engrs. Club, June 4, 1904; Eng. News, Jan. 5, 1905).—**Water-Proof Compositions.**—Asphalt fluid coatings are useful for reservoir walls, concrete foundations, brick, wood, etc. Asphalt only partly dissolves in petroleum naphtha, but heated in a steam-jacketed kettle and not thinned out too much, a mixture of the two may be obtained in which the part of the asphalt not dissolved is held in suspension. Asphalt is entirely soluble in benzol or tuluol which are about the cheapest solvents for all the constituents of asphalt. Tar and pitch are sometimes used in this connection, but tar contains water, light oils, and free carbon, and does not wear as well as good refined asphalt; and pitch contains free carbon, which is sometimes objectionable when thinned out with a solvent. The asphalt alone is somewhat pervious to water, and this is improved by adding about one-fourth its weight of paraffin, and made better if in addition a little boiled linseed oil is added also. For thicker compositions, where body is required, asbestos stone powder, cement, etc., may be added as fillers. Lutes of linseed oil thickened with clay, asbestos, red or white lead, etc., are water-proof if made thick enough. These are much used for steam joints. Flaxseed meal made into a paste with water is often serviceable, the oil contained serving as a binder as the water evaporates. **Oil-Proof Compositions.**—The most useful lute for small leaks, etc., is the well-known "hekto graph composition," as follows: Good glue or gelatin (2 parts), glycerine (1), water (7); this is applied warm and stiffens quickly on cooling. Another composition: a stiff paste of molasses and flour. Another preparation impervious to oil vapors is the "flaxseed poultice," mentioned above, which is proof to oil vapors. A stiff paste of glycerine and litharge makes one of the strongest cements (oil-proof, water-proof, acid-proof, etc.), forming a chemical combination and setting in a few minutes; if a little water is added it sets more slowly, often an advantage; it is mixed when required for use. Plaster of Paris wetted, by itself, or mixed with asbestos, straw, hair, etc., is useful. A solution of silicate of soda made into a stiff paste with carbonate of lime, hardens in 6 to 8 hours. **Acid-Proof Compositions.**—Several kinds given. **Other Proof Compositions.**—For hydrocarbon gases; chlorine; general purposes. Elastic cements; marine glue; gasket compositions; leather cements, stone, iron and crucible cements; etc.

Cost of Portland Cement.—Portland cement, in and around New York, costs from \$1.10 to \$1.25 per barrel, depending upon the quality and quantity required. The price varies greatly according to locality.

A Cement Which is Proof Against Sea-Water (By S. B. Newberry. Cement Age, Jan., 1907; Eng. News, Dec. 12, 1907).—This cement is an iron-ore cement and has been manufactured for several years in Germany. Its composition, as compared with an average commercial Portland is as follows:

	Portland Cement.	Ore-Port. Cement.		Port. Cem.	Ore- Port.
Silica	22.0	20.5	Magnesia ..	1.5	1.5
Alumina	8.0	1.5	Sulph. Anhyd.	1.5	1.0
Iron Oxid	2.5	11.0	Alkalies, etc.	1.0	1.0
Lime	63.5	63.5			
				100.0	100.0

23.—QUARRYING.

When a quarry, of whatever nature, is proposed to be opened, the site should be studied carefully with two main points in view, namely, (1) the most economic methods of mining the material, and (2) the best and cheapest means of transporting the product when mined. It is well to remember that of the two methods of transportation—water and rail—the former is the great "leveler" in the equalization or adjustment of freight rates. Consideration must also be had to water-supply and drainage, whether the machinery is operated by electric- or steam power. On opening the quarry, the surface stripping, consisting of organic and decomposed mineral matter, should be removed ahead of the quarrying. The cost of stripping and removing the weathered rock is usually a very considerable item, and in new quarries opened for local work this cost must be proportioned to the total yardage required.

Sand and Gravel.—An ideal sand and gravel plant is one in which the bank is sufficiently elevated to allow of hydraulic operations. The stream or streams of water may be furnished by gravity or by pumping. The gravel and sand are sluiced into revolving screens of two or more sizes which sort the material, and from which it passes into the bunkers, ready to be loaded on scows or cars. The revolving screens are not very durable and probably the best are common steel plate, perforated. The holes are punched the required size for sorting out the sand and gravel. The material as it passes into the bunkers is thoroughly washed and hence clean and ready for use.

The C. O. Bartlett and Snow Co., of Cleveland, Ohio, manufacture a movable combined gravel digging and screening plant, operated on a track. The particular machine illustrated in *Eng. News*, May 12, 1904, weighs 25 tons, is equipped with a 25-HP. engine and boiler, and has a capacity of 30 to 40 cu. yds. per hour. "The gravel and sand are discharged from the elevator buckets into a belt conveyor, which delivers to a rotary screen. The screen discharges into bins, from which the material is drawn off into gondola cars or wagons." The fine dirt, or dust, is rejected by a belt conveyor to a waste dump. The excavating buckets have a capacity of about three-fourths of a cubic yard.

Rip-rap.—This class includes all rock which may be irregular in size and shape, and especially used for "filling" in breakwater construction, rock-fill dams, slope walls, paving, and crushing into broken stone for concrete, etc. The idea in blasting this material is thoroughly to loosen as much of it as possible for the labor of drilling and cost of explosives, hence the blasts are usually heavy and deep seated. Dynamite high in nitroglycerin, say 75%, is best.

Block Stone.—Building stone is quarried in sizes considerably larger than the finished dimensions required, in order to allow for necessary waste in squaring and dressing. There are four methods employed, each one of which is economically suited to the special nature of the quarry, the material, and the product desired.

Hand Tools are employed where the stone is bedded in thin layers and can be worked with pick, sledge and bar, and by hand-drilling and wedging. Flagstones, for sidewalks, are easily hand-quarried, being a thin-bedded sandstone; also some limestones, shales, etc.

Channeling Machines are used in quarrying blocks of sandstone, limestone and marble. In many quarries the rock is bedded in various commercial thicknesses, the channels are cut to the required depth, and the blocks are wedged off in dimensions as ordered.

The first method used was that of "broach channeling" which consists of drilling rows of holes spaced about an inch apart, and then breaking down these spaces by means of a tool called a "broach."

The "Steel Gang" channeler consists of a gang of tools or chisels arranged side by side and forming a narrow cutter several inches in length. Fig. 1 shows a "swivel head" channeler, size Z, with boiler, manufactured by the Sullivan Machinery Co., of Chicago. This company also manufactures the "rigid-head" channeler, used for vertical cutting, and the "undercutting" channeler, used for horizontal cutting; also various special types.

Fig. 1.

The many recent improvements in channeling machines have rendered them valuable not only in quarrying dimension stone but also in certain classes of rock excavation, notably in the excavation of channels or waterways through solid rock, sinking of large pits or shafts, etc., for water power, and in general where the sides of the finished work are required to be fairly smooth or regular.

The Z machine, together with all the Sullivan channelers of other types, may be operated by compressed air as well as steam. Air is preferable under conditions necessitating the use of a number of machines at points distant from the central power plant and from each other. In this case a suitable reheater is mounted on the machine to secure the utmost efficiency. The Z channeler used in constructing the wheel pits at Niagara Falls and the great canal of the Lake Superior Power Co., at Sault Ste. Marie, were driven by air as above described.

The approximate amount of air at 80 pounds pressure necessary to operate the Y and Z channelers is, without reheating, about 350 feet per minute. The size 6½ machine will use about 300 feet under the same conditions, while the VX channeler will use approximately 200 feet.

Explosives are employed principally in quarrying the harder rocks, as granite, syenite, trap, etc.; but they are used extensively also in quarrying sandstone, limestone and marble, in the smaller quarries where cannelling machines have not been introduced. In blasting, the explosive must not be so violent as to shatter the detached portions too much, hence a coarse gunpowder is mostly preferred instead of the instantaneous dynamite. Where dynamite is used it is generally of the lower grades, containing say 30 to 40% nitroglycerin for ordinary work, unless large masses of very heavy rock, like granite, are to be opened up, in which case 60% dynamite or even 75% dynamite is sometimes used. The liquid nitroglycerin so useful in submarine blasting is seldom employed in quarrying, being too violent, as well as dangerous to handle. Large blocks, detached from the quarry by blasting, are subsequently broken up into the required dimension, by drilling holes in line and wedging, that is, by plug and feather.

Rock Drills used in quarrying may be classed under three heads, as follows:

The Hammer- or "Jumper" Drill, which includes the smaller sizes such as may be operated by one man who also wields the hammer, weighing say 4½ lbs.; and also the larger sizes or jumpers proper, which are operated by one man turning and with two men striking (4½-lb. and 10-lb. hammers for two hand drilling, and two 10-lb. hammers for three-hand drilling).

The "Churn" Drill, a heavy drill 6 to 8 ft. in length, operated usually by two or three, sometimes six, men who raise the drill, let it fall into the hole, catch it on the rebound, etc.—the most economical hand drill for moderately deep holes, when nearly vertical.

Fig. 2.

The "Percussion" Drill, which is simply a churn drill attached to the piston of a steam- or compressed air cylinder, and by far the most effective drill for quarrying, mining, tunneling and general rock excavation. Fig 2 illustrates a percussion drill of the Ingersoll-Rand type mounted on a "quarry bar," which arrangement is specially useful for drilling "plug and feather" holes, for "broaching" in granite and similar materials, for taking out "key blocks," for "lofting" work in quarrying material with a well defined cleavage, and for general contract work. The "Light 3-inch" bars have a length (over all) of 10 ft., a cutting length of 8 ft.-4 ins., are suitable for 2-2½ in. cyl. dia. of drill, and weigh, with weights but without drill, 945 lbs. The "Standard 4½-inch" bars have a length (over all) of 12 ft., a cutting length of 10 ft., are suitable for 2½-3½ in. cyl. dia. of drill, and weigh, with weights but without drill, 1625 lbs. The price of the Light bars is \$175.00 and of the Standard bars \$250.00.

Table 2, page 424, gives dimensions and weights of the Rand "Little Giant" percussion drill (Fig. 3).

* Percussion drills may be mounted on the "tripod," which is a most common method; on the "column" or vertical bar; and on the "gadder" or adjustable carriage designed especially for quarry work where parallel holes are to be drilled in any plane. "Used in connection with the channeler it is applied in 'lofting,' or drilling the horizontal undercutting holes in material which has been channeled. Used in 'plug and feather work,' it breaks the large blocks cut free by the channelers." (See page 436.)

Compressed Air, used directly in splitting granite and creating working beds in the quarry, is a recent novelty practised successfully by the North Carolina Granite Corporation at Mt. Airy, N. C., and described fully in "Mine and Quarry"† of May, 1905. The quarry consists of a solid mass of granite without cleavage planes or beds in any direction and the compressed air is used to create artificial beds to which to work:

In the center of the sheet or area to be lifted, a drill hole two or three inches in diameter is sunk six or eight feet in depth, depending on the *greatest thickness* of stone required. The bottom of the hole is enlarged into a pocket by exploding half a stick of dynamite. A small charge of powder, about a handful, is then exploded in the pocket, thus starting a horizontal crack or cleavage across its greater diameter. Charges increasing in size are now exploded in the cavity, the drill hole being plugged at each blast, to confine the powder gases and thus exert a more or less constant force upon the stone. After the cleavage has extended to a radius of 75 or 100 feet in all directions, a pipe is cemented into the hole and connected by means of a globe valve, to the air pipe line from an air compressor. Compressed air at 70 to 80 pounds pressure is gradually admitted and the cleavage rapidly extended until it comes out upon the hillside in a thin edge. A sheet of several acres in extent may be raised in this manner, affording a bed plane approximately horizontal, to which the quarrymen can work, thus securing stone of any required thickness. . . . The time [formerly] required for extending the cleavage by powder for 100 feet was between two and three weeks, while to split the larger area, between 100 and 225 feet radius, required only half an hour when compressed air was used. . . . Its equipment is modern in every respect, and includes 35 plug† drills, 3 Sullivan tripod drills, 4 Sullivan quarry bars, 15 surfacing machines, and 60 small hand tools. These are all operated by air power from a Sullivan Corliss air compressor of the two stage type, with a piston displacement of 2000 cubic feet of free air per minute at 78 r.p.m., against 80 to 100 pounds terminal pressure. The dimensions of the compressor are as follows: Steam cylinders, 16 and 28 in. by 42 in. stroke; air cylinders, 26 and 16 in. by 42-in. stroke.

Cost of Quarrying Rubble and Dimension Stone for the Buffalo, N. Y., Breakwater (By Emile Low. Eng. News, Oct. 20, 1904.—Tabulated costs, method of quarrying, and plant used are given. The cost for explosives, which includes powder, dynamite and fuses, per ton of stone, all kinds, quarried was: For May (1903), 1.3 cts.; July (1903), 2.0 cts.; August (1903), 2.1 cts. About 1 lb. of powder was used for every 7 tons of stone quarried, and 1 lb. of dynamite for every 67 tons of stone. One fuse was used for every 5½ tons of stone quarried. Total cost of quarrying 1 ton of stone, loading and placing same aboard of scows, as follows: Labor, 33 cts.; coal, 4 cts.; explosives, 2 cts.; miscellaneous, 5 cts.; total, 44 cts. This is exclusive of cost of plant and deterioration.

* Pneumatic drills for hand service, like pneumatic riveters, are the latest development in rock drilling by machinery. They go by the various names of "Little Jap," "Little Imp," and "Plug" drills, and do remarkable work.

† Published by the Sullivan Machinery Co., Chicago.

‡ The plug drill is a pneumatic power drill for hand service similar to other pneumatic hand tools, as the pneumatic riveter, etc.

24.—STONE CUTTING.

The following is from the report of the American Society's Committee* to secure uniformity of terms. The matter is re-arranged for convenience, in parallel columns.

STONES CLASSED ACCORDING TO FINISH.

All stones used in building are divided into three classes, according to the finish of the surface, viz.:

- I. Rough stones that are used as they come from the quarry.
- II. Stones roughly squared and dressed.
- III. Stones accurately squared and finely dressed.

In practice, the line of separation between them is not very distinctly marked, as one class gradually merges into the next.

I. Unsquared Stones. — This class covers all stones which are used as they come from the quarry, without other preparation than the removal of very acute angles and excessive projections from the general figure. The term "backing" which is frequently applied to this class of stone, is inappropriate, as it properly designates material used in a certain relative position in a wall, whereas stones of this kind may be used in any position.

TOOLS EMPLOYED.

The *Hand Hammer*, weighing from 2 to 5 pounds is used in drill-

Fig. 1.

ling holes, and in pointing and chiseling the harder rocks.

The *Plug*, a truncated wedge of steel, and the *Feathers* of half-

Fig. 2.

round malleable iron are used for splitting unstratified stone. A row of holes is made with the *Drill* on the line on which the fracture is to be made; in each of these holes two feathers are inserted, and the plugs lightly driven between them. The plugs are then gradually driven home by light blows of the hand hammer on each in succession until the stone splits.

Drills.

Fig. 3.

The *Double Face Hammer* is a heavy tool weighing from 20 to 30 pounds, used for roughly shaping

Fig. 4.

stones as they come from the quarry and for knocking off projections. This is used only for the roughest work.

* Trans. Am. Soc. C. E., vol. vi., p. 297.

II. Squared Stones.—This class covers all stones that are roughly squared and roughly dressed on beds and joints. The dressing is usually done with the face hammer or ax, or in soft stones with the tooth-ax. The distinction between this class and the third lies in the degree of closeness of the joints which is demanded. Where the dressing on the joints is such that the distance between the general planes of the surfaces of adjoining stones is one-half inch or more, the stones properly belong to this class.

(a) **Quarry-faced stones** are those whose faces are left untouched as they come from the quarry.

(b) **Pitch-faced stones** are those on which the arris is clearly defined by a line beyond which the rock is cut away by the pitching chisel, so as to give edges that are approximately true.

(c) **Drafted Stones** are those on which the face is surrounded by a chisel draft, the space inside the draft being left rough. Ordinarily, however, this is done only on stones in which the cutting of the joints is such as to exclude them from this class.

In ordering stones of this class the specifications should always state the width of the bed and end joints which are expected, and also how far the surface of the face may project beyond the plane of the edge. In practice, the projection varies between 1 inch and 6 inches. It should also be specified whether or not the faces are to be drafted.

The *Face Hammer* has one blunt and one cutting end, and is used for the same purpose as the

Fig. 5.

double face hammer where less weight is required. The cutting end is used for roughly squaring stones, preparatory to the use of finer tools.

The *Cavil* has one blunt and one pyramidal, or pointed, end, and weighs from 15 to 20 pounds.

Fig. 6.

It is used in quarries for roughly shaping stone for transportation.

The *Pitching Chisel* is usually of $1\frac{1}{2}$ -inch octagonal steel, spread on the cutting edge to a rectangle of $\frac{1}{2} \times 2\frac{1}{2}$ inches. It is used to make a

Pitching Chisel.

Fig. 7.

Chisel.

Fig. 8.

well-defined edge to the face of a stone, a line being marked on the joint surface to which the chisel is applied and the portion of the stone outside of the line broken off by a blow with the hand-hammer on the head of the chisel.

The *Chisel*, of round steel of $\frac{1}{4}$ to $\frac{1}{2}$ inch in diameter and about 10 inches long, with one end brought to a cutting edge from $\frac{1}{4}$ inch to 2 inches wide, is used for cutting drafts or margins on the face of stones.

The *Tooth Chisel* is the same as the chisel, except that the cutting edge is divided into teeth. It is used only on marbles and sandstones.

Tooth Chisel.

Fig. 9.

Splitting Chisel.

Fig. 10.

The *Splitting Chisel* is used chiefly on the softer, stratified stones, and sometimes on fine architectural carvings in granite.

III. Cut Stones.—This class covers all squared stones with smoothly dressed beds and joints. As a rule, all the edges of cut stones are drafted, and between the drafts the stone is smoothly dressed. The face, however, is often left rough when the constructions are massive.

Rough-pointed.—When it is necessary to remove an inch or more from the face of a stone, it is

Rough-Pointed.

Fig. 12.

done by the pick or heavy point until the projections vary from $\frac{1}{2}$ inch to 1 inch. The stone is then said to be rough-pointed. In dressing limestone and granite, this operation precedes all others.

Fine-pointed.—If a smoother finish is desired, rough pointing is followed by fine pointing. It is done with a fine point.

Fine-Pointed.

Fig. 14.

pointing is used only where the finish made by it is to be final, and never as a preparation for a final finish by another tool.

Crandalled.—This is only a speedy method of pointing, the effect being the same as fine pointing,

Fig. 16.

except that the dots on the stone are more regular. The variations of level are about $\frac{1}{4}$ inch, and the rows are made parallel. When other rows at right angles to the first are introduced, the stone is said to be *cross-crandalled*.

The *Mallet* is used [instead of the hand hammer, in pointing,

Mallet.

Fig. 11.

chiseling, etc.] where the softer limestones are to be cut.

The *Pick* somewhat resembles the pick used in digging, and is used for rough dressing, mostly on

Fig. 13.

limestone and sandstone. Its length varies from 15 to 24 inches, the thickness of the eye being about 2 inches.

The *Point* is made of round or octagonal rods of steel, from $\frac{1}{4}$ inch to 1 inch in diameter. It is made

Point.

Fig. 15.

about 12 inches long with one end brought to a point. It is used until its length is reduced to about 5 inches. It is employed for dressing off the irregular surface of stones, either for a permanent finish or preparatory to the use of the ax. According to the hardness of the stone, either the hand-hammer or the mallet is used with it.

The *Crandall* is a malleable-iron bar about 2 feet long, flattened at one end. In this end is a slot,

Crandall.

Fig. 17.

3 inches long and $\frac{1}{4}$ inch wide. Through this slot are passed ten double-headed points of $\frac{1}{4}$ -inch squared steel, 9 inches long, which are held in place by a key.

hammered, and these two vary for smoothness of produced. The

a patent hammer 12 to the inch; specifications the inch must be 8-cut, 10-cut, of axing is to chisel marks, parallel as far as is a final finish.

The *Ax*, or *Pean Hammer*, has two opposite cutting edges. It is used for making drafts around the arris, or edge, of stones, and in

Fig. 19.

reducing faces, and sometimes joints, to a level. Its length is about 10 inches, and the cutting edge about 4 inches. It is used after the point and before the patent hammer.

The *Patent Hammer* is a double-headed tool so formed as to hold at each end a set of wide thin chisels. The tool is in two parts, which are held together by the bolts which hold the chisels. Lateral motion

Fig. 20.

is prevented by four guards on one of the pieces. The tool without the teeth is $5\frac{1}{2} \times 2\frac{1}{4} \times 1\frac{1}{4}$ inches. The teeth are $2\frac{1}{4}$ inches wide. Their thickness varies from $\frac{1}{2}$ to $\frac{1}{4}$ of an inch. This tool is used for giving a finish to the surface of stones.

the tooth-ax is of points, and of a stone in as fine pointing. ever, only a pre-hammering, and done without long as the surface efficiently leveled.

The *Tooth Ax* is like the ax, except that its cutting edges are divided into teeth, the number of

Fig. 21.

which varies with the kind of work required. This tool is not used in granite and gneiss cutting.

Bush-hammered.—The roughnesses of a stone are pounded off by the bush hammer, and the stone is then said to be "bushed." This

Fig. 22.

kind of finish is dangerous on sandstone, as experience has shown that sandstone thus treated is very apt to scale. In dressing limestone which is to have a bush-hammered finish, the usual sequence of operation is (1) rough-pointing, (2) tooth-axing, and (3) bush-hammering.

Rubbed.—In dressing sandstone and marble, it is very common to give the stone a plane surface at once by the use of the stone-saw. Any roughnesses left by the saw are removed by rubbing with grit or sandstone. Such stones, therefore, have no margins. They are frequently used in architecture for string-courses, lintels, door-jambs, etc.; and they are also well adapted for use in facing the walls of lock-chambers and in other localities where a stone surface is liable to be rubbed by vessels or other moving bodies.

Diamond Panels.—Sometimes the space between the margins is sunk immediately adjoining them, and then rises gradually until the four planes form an apex at the middle of the panel. In general, such panels are called diamond panels, and the one just described is called a sunk diamond panel. When the surface of the stone rises gradually from the inner lines of the margins to the middle of the panel, it is called a raised diamond panel. Both kinds of finish are common on bridge quoins and similar work. The details of this method should be given in the specifications.

The *Bush Hammer* is a square prism of steel whose ends are cut into a number of pyramidal points. The length of the hammer is from

Fig. 23.

4 to 8 inches, and the cutting face from 2 to 4 inches square. The points vary in number and in size with the work to be done. One end is sometimes made with a cutting edge like that of the ax.

The *Machine Tools* used chiefly are the saws, planers, grinders, polishers, etc.

I. STONE MASONRY.

Definitions of Parts of Wall.†—*Face*, the front surface of a wall; *Back*, the inside surface. *Facing*, the stones which form the face or outside of the wall; *Backing*, the stones which form the back of the wall; *Filling*, the interior of the wall. *Batter*, the slope of the surface of the wall; as, 1 on 12—1 inch horizontal to 1 foot vertical. *Course*, a horizontal layer of stone in

* Progress report. Published by permission.

† See Trans. Am. Soc. C. E., Vol. VI., as previously referred to under Sec. 24, Stone Cutting.

the wall. If the stones of each layer are of equal thickness throughout it is termed "regular coursing;" if the thicknesses are unequal, the term "random" or "unequal coursing" is applied. *Joints*, the mortar layer between the stones. The horizontal joints are called "bed-joints," or simply "beds;" the vertical joints are sometimes called "builds." Usually the horizontal joints are called "beds" and the vertical ones "joints." *Coping*, a projecting course of heavy stones on the top of the wall to protect it. (A "weathered" coping is one whose top is beveled so as to act as a roof). *Pointing*, a better quality of mortar put in the face of the joints to help them resist weathering. *Bond*, the arrangement of stones in adjacent courses. *Stretcher*, a stone whose greatest dimension lies parallel to the face of the wall. *Header*, a stone whose greatest dimension lies perpendicular to the face of the wall. *Quoin*, a corner stone; a header for one face and a stretcher for the other. *Dowels*, straight bars or pins of iron which enter a hole in the upper side of one stone and also a hole in the lower side of the stone next above (for lateral stability). *Cramps*, bars of iron having the ends turned at right angles to the body of the bar, which ends enter holes in the upper side of adjacent stones.

Definitions of Kinds of Masonry.*—(For classification of Stones, see Sec. 24, Stone Cutting).

Rubble Masonry.—Masonry composed of unsquared stone, Fig. 1.

Uncoursed rubble.—Masonry composed of unsquared stones laid without any attempt at regular courses. Fig. 1.

Coursed rubble.—Unsquared-stone masonry which is leveled off at specified heights to an approximately horizontal surface (as at a, b, etc., Fig. 1).

(**Squared rubble.**—Rubble masonry in which the stone may be required to be roughly shaped with the hammer, so as to fit approximately.)

Squared-Stone Masonry.—Masonry in which the stones are roughly squared and roughly dressed on beds and joints. (If the joints are as small as about one-half inch the classification might come under that of Ashlar).

There are five kinds.

Regarding character of face:

Quarry-faced masonry.—Face of stone is left as it comes from the quarry.

Pitch-faced masonry.—Face of stone is roughly dressed.

Fig. 1.

Fig. 2.

Fig. 3.

Fig. 4.

Regarding character of course:

Range-work (Fig. 2).—Masonry laid in continuous courses throughout.

Broken Range-work (Fig. 3).—Masonry laid in courses non-continuous or broken.

Random-work (Fig. 4).—Masonry not laid in courses at all.

Ashlar Masonry.—"Cut-stone masonry," or masonry composed of any of the various kinds of cut stone mentioned under Stone Cutting, Sec. 24. From its derivation ashlar apparently means large, square blocks; but practice seems to have made it synonymous with "cut-stone," and this secondary meaning has been retained for convenience.

Fig. 5 represents the face of an ashlar wall, coursed throughout. **Broken Ashlar** (Fig. 6).—Cut-stone masonry in which the joints are not continuous.

* See Trans. Am. Soc. C. E., Vol. VI., as previously referred to under Sec. 24, Stone Cutting.

Fig. 5.

Fig. 6.

Small Ashlar.—Cut-stone masonry in which the stones are less than one foot in height; seldom used.

Rough Ashlar.—A term sometimes given to squared stone masonry, either "quarry-faced" or "pitch-faced" when laid as *range-work*, but it is more logical and more expressive to call such masonry *squared range-work*.

Dimension Stones.—Cut-stones, all of whose dimensions have been fixed in advance. If the specifications for ashlar masonry are so written as to prescribe the dimensions to be used, it will not be necessary to make a new class of such stones.

Range-work, whether of squared stones or of ashlar, is usually backed up with rubble masonry, which in such cases is specified as *Coursed Rubble*.

Whatever terms are employed in common use to various classes of masonry, it is not safe to trust to them alone in preparing specifications for construction, but every specification should contain an accurate description of the character and quality of the work desired. Whenever practicable, samples of such kind of cutting and masonry should be prepared beforehand, and exhibited to the persons who propose to undertake the work.

Specifications for Stone Masonry.—The following is a Committee Report* (amendments included) submitted to the Am. Ry. Eng. and M. W. Assn., March 1906, but has not formally been approved by the Association.—See *Proceedings*, Vol. 7.

GENERAL.

Stone.—1. Stone masonry shall be built of the kinds specially designated, with such arrangements of courses and bond as shown on the drawings or as directed. The stone shall be hard and durable, free from seams or other imperfections, of approved quality and shape, and in no case have less bed than rise, and shall be laid on their broadest beds, well bonded and solidly bedded. When liable to be affected by freezing, no unseasoned stone shall be laid.

Dressing.—2. Dressing shall be the best of the kind specified for each class of work. 3. Beds and joints or builds shall be square with each other, and dressed true and out of wind. Hollow beds will not be allowed. 4. All stones shall be dressed for laying on natural bed. 5. Marginal drafts should be neat and accurate. 6. Pitching shall be done to true lines and exact batter.

Mortar.—7. The sand and cement shall be mixed dry and in small batches in proportions as directed, on a suitable platform, which must be kept clean and free from all foreign matter; then water is to be added, and the whole remixed until the mass of mortar is thoroughly homogeneous, and leaves the hoe clean when drawn from it. It shall not be retempered after it has begun to set. Mechanical mixing to produce the same results may be permitted.

Laying.—8. All stones shall be laid on natural beds. Each stone shall be settled into place in full bed of mortar. 9. No stone shall be dropped or slid over the wall, but shall be placed without jarring the stones already laid. 10. No heavy hammering shall be allowed on the wall after a course is laid. 11. If a stone becomes loose after the mortar is set, it shall be relaid with fresh mortar. 12. Each stone shall be cleansed and dampened before laying. 13. Stones shall not be laid in freezing weather unless allowed by the engineer. If allowed, they shall be free from ice, snow or frost by warming, and laid in mortar made of heated sand and water, or, with proper precautions, mixed with brine in proportions of one lb. of salt to 18 gals. of water, when the temperature is 32° F. Add one ounce of salt for every degree of temperature below 32° F. 14. Stones shall be laid to exact lines and levels so as to give the required bond and thickness of mortar in beds and joints.

* Published by permission of the Executive Committee, through the courtesy of Mr. E. H. Fritch, Secretary.

Pointing.—15. Mortar in beds and joints of exposed faces shall be removed to a depth of not less than one in. before it has set. No pointing shall be done until the wall is complete and mortar set, nor when frost is in the stone. Wet the joints and fill again with mortar made of equal parts sand and Portland cement. It shall be pounded in with "set-in" or calking tool, and finished with a beading tool the width of the joint, used with a straight-edge.

CLASSIFICATION.

16. Stone masonry shall be classified under the following heads: Bridge and Retaining Wall Masonry, Arch Masonry, Culvert Masonry, and Dry Masonry.

Bridge and Retaining Wall Masonry.

17. Bridge and Retaining Wall masonry shall consist of two classes: (a) Ashlar (either coursed or broken-coursed), and (b) Rubble.

(a) Ashlar Masonry in Bridges and Retaining Walls.

18. In Ashlar masonry in bridges and retaining walls (either coursed or broken-coursed), the stone shall be large and well-proportioned. 19. No course shall be less than 14 ins. nor more than 30 ins. thick; the thickness of courses to diminish regularly from bottom to top.

Dressing.—20. The beds and joints or builds of face stones shall be fine-pointed, so that the mortar layer shall not exceed $\frac{1}{2}$ in. in thickness when the stones are laid. 21. Joints in face stones shall be full to the square for a depth equal to at least $\frac{1}{2}$ the height of the course, but in no case less than 12 ins.

Facing or Surface Finish.—22. The exposed surface of each face stone will be rock-faced, and the edges pitched to true lines and exact batter; the face to have no projections over 3 ins. beyond the pitch lines. 23. A chisel draft $1\frac{1}{2}$ ins. wide shall be cut at each exterior corner. 24. No holes for stone hooks shall be permitted to show in exposed surfaces. They must be handled with clamps, keys, lewis or dowels.

Stretchers.—25. Stretchers shall be not less than 4 ft. long, and to have at least $1\frac{1}{4}$ times as much bed as thickness of the course.

Headers.—26. Headers shall be not less than 4 ft. in length. They shall occupy one-fifth of the face of the wall, and no header shall have less than 18 ins. width of face, and when the course exceeds 18 ins. height, the width of face shall be not less than the height of course. Headers shall hold the size in the heart of the wall that they show on the face, and be so arranged that a header in a superior course shall be placed between two headers in a course below; but no header shall be laid over a joint, and no joint shall cover a header. They shall be similarly disposed in the back of the wall, interlocking with those in the face when the thickness of the wall will admit. When the wall is too thick to admit of such arrangement, stones of not less than 4 ft. in length shall be placed transversely in the heart of the wall to bond the two opposite sides of it.

Backing.—27. Backing shall be large, well-shaped stone, roughly bedded and jointed; the bed joints not to exceed 1 in., and vertical joints generally not to exceed 2 ins. No part or portion of vertical joints shall have a greater dimension than 6 ins., which void shall be thoroughly filled with spalls full bedded in cement mortar or filled with concrete. At least one-half of the backing stones shall be of the same size and character as the face stone and with parallel beds. 28. When face stone is backed with two courses, neither course shall be less than 8 ins. thick. 29. When the wall is 3 ft. thick or less, the face stone shall pass entirely through and no backing be allowed. 30. If the engineer so directs, the backing may be entirely of concrete, or back laid with headers and stretchers, as specified above, and heart of wall filled with concrete.

Bond.—31. The bond of stone on face, back and heart of wall shall not be less than 12 ins. Backing shall be laid to break joints with the face stone and with one another.

Coping.—32. Coping shall be dimension stone, holding full size throughout, proportioned for its loading, as marked on the drawings. 33. The beds, joints and top shall be fine-pointed. 34. The location of joints shall be determined by the position of the bed plates, and must be shown on the drawings.

Locks.—35. When required, in the judgment of the engineer, coping stones, stones in the wings and abutments, and stones on piers shall be secured together with iron clamps or dowels, their position being indicated by the engineer.

able Masonry in Bridges and Retaining Walls.

idge- and retaining-wall masonry shall consist of stones laid in irregular courses. The beds shall be parallel, and lie horizontally in the wall. The bottom stones shall be flat stones. The wall shall be compactly laid, having at surface of the back and face headers, so arranged as to fill the spaces in the heart of the wall filled with suitable mortar, thoroughly bedded in cement mortar or filled with concrete. The joints must not be more than 1 in. in thickness.

Arch Masonry.

Arch masonry shall consist of the arch ring only, or that portion of the arch and extrados, and shall be of two classes: (a) Ashlar Arch Masonry. (b) Rubble Arch Masonry.

(a) Ashlar Arch Masonry.

The voussoirs shall be of full size throughout, and must have bond and be dressed true to templet. 39. The depth and depth of voussoirs shall be shown on the drawings. The voussoirs and the intrados shall be fine-pointed. The joints must not exceed $\frac{3}{4}$ in. 41. The exposed surface of the ring shall be smooth or rock-faced, with a marginal draft. 42. Voussoirs shall be laid simultaneously from both bench walls. 43. Backing shall consist of large stones shaped to fit the arch bonded to the spandrel with mortar. Concrete may also be used for backing. If required, a thin coat of mortar or grout shall be applied upon which shall be placed a covering of suitable waterproofing material. 45. Centers shall not be struck until directed. The arch, spandrels, parapets, wing walls and copings shall conform to the specifications for Ashlar Masonry in Bridges and Retaining Walls.

(b) Rubble Arch Masonry.

The voussoirs shall be full size throughout, and must have bond and be dressed true to templet. 48. The depth of voussoirs shall be shown on the drawings. The beds need only be roughly dressed so as to bring the joints to a true line. 50. Mortar joints shall not exceed 1 in. 51. The exposed surface of the ring shall be smooth or rock-faced, and the edges pitched. Voussoirs shall be carried up simultaneously from both bench walls. Backing shall consist of large stones shaped to fit the arch bonded to the spandrel with mortar. Concrete may also be used for backing. 54. If waterproofing is required, a thin coat of mortar or grout shall be applied for a finishing coat upon which shall be placed a covering of suitable waterproofing material. 56. Bench walls, parapet and wing walls shall be built under the arch in Rubble Masonry in Bridges and Retaining Walls.

Culvert Masonry.

Culvert masonry shall be laid in cement mortar. The character and quality of work shall be similar to that specified for Rubble Masonry in Bridges and Retaining Walls. 58. One-half the top stones shall extend entirely across the wall. 59. The covering shall be of strong stone at least 12 ins. thick, or as shown on drawings. The joints shall be roughly dressed so as to make close joints with each other. 60. End walls shall be covered with suitable coping.

Dry Masonry.

Dry masonry shall include: (a) Dry Ret'g Walls, and (b) Slope Walls.

(a) Dry Retaining Walls.

Retaining walls shall include all dry rubble work for retaining earth. 63. Flat stone at least twice as wide as high. The beds and joints to be roughly dressed square to each other. 64. Joints not to exceed $\frac{3}{4}$ in. 65. The different courses shall be evenly distributed over the whole face of wall, generally the largest stone in the lower part of wall. 66. The work shall be laid and present a reasonably true and smooth surface, free from projections. The wall is double-faced and self-sustaining.

(b) Slope Walls.

67. Slope walls shall be built of such thickness and slope as may be required by the engineer. No stones shall be used which do not reach through the wall. Stones shall be placed at right angles to the slopes. This wall is single-faced and built with steep slope simultaneously with the embankment which it is to protect.

Quantity of Masonry in Abutments.—Tables 1 and 2, following, were calculated from Fig. 7. Table 1 gives the quantities of masonry and steel in one abutment of various heights, and Table 2 is a supplementary table to facilitate the reduction of these quantities to weights.

100	391.5	418.5	432.	2000.	2167.	2333.	
200	783.	837.	864.	4000.	4333.	4667.	
300	1174.5	1255.5	1296.	6000.	6500.	7000.	
400	1566.	1674.	1728.	8000.	8667.	9333.	
500	1957.5	2092.5	2160.	10000.	10833.	11667.	
1000	3915.	4185.	4320.	20000.	21667.	23333.	

*Ans.—From columns 1, 3 and 6 in above table we have: Weight = (masonry) 1607.04 × 1000 + (steel) 18460 = 1,625,500 lbs. = 812.75 tons.

II. BRICK MASONRY.

Bond.—The terms "header" and "stretcher" are used in brickwork as in stonework. The "bond" of a brick wall depends upon the arrangement of headers and stretchers, in the same or in adjacent courses.

English Bond (Fig. 8).—Alternate entire courses of headers and stretchers.

Modified English Bond.—Each course consisting entirely of headers or of stretchers, but not alternating as above; usually one course of headers to every four to six courses of stretchers. (Where wall is laid with one course of headers to every two or three courses of stretchers it is generally classed as English bond).

Flemish Bond (Fig. 9).—Each course made up of alternate headers and stretchers.

English bond is considered the strongest.

Brickwork is well adapted to all kinds of masonry construction where excessive strength and massive weight (as bridge abutments, piers, dams, etc., which call for concrete and stonework) are not particularly essential. Hence its use in building-walls (including the upper stories in tall buildings), tunnel linings, small arches, culverts, (street paving), sewers, etc. The convenience in handling and laying brick, in forming arches and "rounding" corners, makes it particularly useful in these classes of construction. In fire-resisting qualities it is superior to any natural building stone, with the exception possibly of sandstone, and is equal to the latter in this respect,

Fig. 8.

Fig. 9.

and infinitely superior to it (i.e., to most varieties) as regards frost action and absorption of moisture. Generally speaking, when compared with stonework, brick masonry lies between ashlar and common rubble masonry, both in cost and strength. Regarding cost, the writer has witnessed the price of common building brick fluctuate during the past year, in Brooklyn, between \$16 and \$7 per thousand. It is perhaps essential to note here that while the higher price was maintained the builders resorted largely to rubble and concrete construction, which finally brought the trust price to the lower figure. This may illustrate also that the "cost of work" obtained from any source must be used with judgment in connection with the details furnished therewith, and with the prevailing local conditions.

The Mortar used in brick masonry may vary considerably, depending upon the class of work. For instance, the best mortar usually specified is composed of 1 part Portland cement, and 2 parts clean, sharp sand, where the structure is exposed to considerable stress; while for the most ordinary brickwork, 1 part fresh, well-slaked lime and 2½ to 3 parts sand, will answer. Between these limits we may have various mixtures of Portland cement, natural cement, common lime, and sand. Thus:

Class	A	1 Port. Cem.	Nat. Cem.	Com. Lime.	2	Clean, sharp Sand.
"	A ₁	1	"	"	2½	"
"	A ₂	1	"	"	3	"
"	B	"	1	"	2	"
"	B ₁	"	1	"	2½	"
"	B ₂	"	1	"	3	"
"	C	"	"	1	2	"
"	C ₁	"	"	1	2½	"
"	C ₂	"	"	1	3	"
"	D	1	"	"	4	"
"	D ₁	1	"	"	5	"
"	D ₂	1	"	"	6	"
"	E etc.	1	"	1 Lime paste	2	"
"	F etc.	"	1	"	2	"

Class A is used in superior building construction, for railroad masonry in general, tunnel lining, and sewers; class E, for building-work of the very highest class; class C, for common brickwork as in buildings. Where cement and lime come in barrels, "barrel" measure may be used in determining the "parts" of cement, lime and sand. Fire brick should be laid in fire-clay mortar. Colored mortar is used for pressed brick facing.

Pressed-brick masonry, for facing, requires less mortar per cubic yard of masonry than the common-brick backing, because pressed bricks are a little larger than the common (which are 8¼x4x2½ standard) to allow for thinner joints.

For any kind of masonry, the bricks should be wet before laying (except perhaps in freezing weather—unless special care is taken to warm the water and sand), and thoroughly bedded in mortar, and pressed or shoved into place.

3.—QUANTITIES OF BRICK AND MORTAR IN BRICK MASONRY.

(Brick, standard size—8¼x4x2½.)

Thickness of Joint.	No. of Brick per Cu. Ft. of Masonry.	No. of Brick per Cu. Yd. of Masonry.	Cu. Ft. of Masonry per 1000 Brick.	Cu. Yds. of Masonry per 1000 Brick.	Cu. Yds. of Mortar per Yd. of Masonry.	Cu. Yds. of Mortar per 1000 Brick.
zero.	23.3	628.4	43.0	1.59	.000	.000
1/8	21.1	568.6	47.5	1.76	.095	.167
1/4	19.1	516.6	52.3	1.94	.180	.350
3/8	17.4	471.0	57.3	2.12	.250	.530
1/2	16.0	430.9	62.6	2.32	.314	.728
5/8	14.6	395.4	68.3	2.53	.371	.939

This table is calculated for massive masonry construction; allowance should be made for thin walls—bricks to increase and mortar to diminish slightly per volume of masonry.

III. CONCRETE MASONRY.

No other class of masonry is so generally employed, especially for massive construction, as concrete. It is almost universally used for footings of heavy structures such as abutments, walls and piers for bridges, revetments (breakwaters), dams, and buildings; while it often enters largely, sometimes wholly, into these structures themselves.

Concrete footings are often reinforced with steel rails or I-beams, in one or more tiers, to distribute the loads (either above or below) more uniformly. Such construction may be said to form the connecting link between plain- and reinforced concrete. See Sec. 50, Foundations.

Rock Crushers are now almost wholly employed in breaking stone for concrete, in place of hand-breaking. By the last-named method a laborer is usually counted upon to break about one cu. yd. of trap or from 2 to 3 cu. yds. of limestone, in sizes to pass through a 2-in. ring, in a 10-hr. day. Much depends upon the size and shape of the rip-rap stone received for breaking. On the other hand, the capacities of machines run up to several hundred tons per day. A cubic yard of broken trap rock, assuming 45% voids, will weigh about $185 \times 27 \times .55 =$ about 2750 lbs. or $1\frac{1}{2}$ tons; while a cubic yard of limestone, assuming 37 $\frac{1}{2}$ % voids, will weigh about the same. Unscreened broken stone, especially of the softer kinds, has less percentage of voids than the screened. The softer rocks in crushing assume a more rounded form, and break into more variable sizes, both of these conditions tending to reduce the percentage of voids. Spheres of uniform size, as cannon balls, may be piled in *large piles* in pyramidal form so that the percentage of voids will approach the lower limit of 25.963% voids.

Permanent crushers, often with extensive plants, are frequently installed at quarries. For this purpose, the gyratory type of crusher is preferred, a single machine being able to turn out as high as 2000 tons or more per 10-hr. day. Such a machine would weigh in the neighborhood of 50 tons, have a receiving opening of say $1\frac{1}{2} \times 5$ ft., and require about 150 H. P. to operate. The smaller machines are less economical in the use of power. A machine of $\frac{1}{2}$ the above capacity would require about $\frac{1}{2}$ the power to operate, and would weigh about 30 tons; a machine of $\frac{1}{3}$ the above capacity would require about $\frac{1}{3}$ the power, and weigh about 20 tons; $\frac{1}{4}$ the capacity, $\frac{1}{4}$ the power, and weigh about 10 tons, etc. The above H. P.'s include power required to operate elevators and screens.

Portable crushers are furnished as low as about 4 tons in weight, with openings for 7×10 in. stone, capacity 50 to 60 tons per 10-hr. day, and requiring about 8 H. P. to operate. Small machines cost about \$8.50 to \$9 per capacity in tons per 10 hr. day. Large machines, from \$7 to \$8.

Hand crushers, costing about \$30, will receive stone up to about $1\frac{1}{2} \times 3$ ins.

The best crushers have jaws of manganese-steel, or other steel of equal hardness.

Concrete Mixers, or machines for mixing concrete, are indispensable at the present day on work of any magnitude. They may be divided into two classes, namely, "fixed" mixers, and "mechanical" mixers.

Fixed or Gravity Mixer consists of a steel trough fixed on an incline of say 4 to 4 $\frac{1}{2}$ ins. horizontal to 12 ins. vertical, and some provided with internal projections in the form of steel pins or baffle plates, which deflect and "mix" the material, fed at the upper end, as it descends. These mixers are economically used in lining the bottoms and sides of reservoirs and in work of similar character where the mixing can be done at an elevation above the place for depositing the concrete.

Mechanical Mixers are of two types: "continuous" mixers, and "batch" mixers. The *continuous* mixers are provided with plows, shovels, or paddles which mix the material as fast as delivered, and discharge the mixture continuously. Portable machines of this type are used economically for street work.

Batch mixers of the rotary type are the most generally used. These machines with engine (gasoline), or engine and boiler (steam), are mounted on skids or on wheels, are very compact, and have a capacity of about 200 batches per 10-hr. day, each batch ordinarily containing $\frac{1}{4}$ yd., $\frac{1}{2}$ yd., or 1 yd., depending on the "size" of the mixer. They are, however, made

in sizes ranging from 2 cu. ft. up to 2 cu. yds. The number of H. P. required is equal to size of batch in cu. yds. multiplied by 15, about. Many of the machines measure the proportions of the ingredients.

The Proportions of Portland Cement, Sand and Broken Stone are, 1 : 2 to 4 : 4 to 8, depending upon the quality of materials used and of the resulting concrete required. A good mix is 1 : 2½ : 5, while 1 : 3 : 6 is perhaps most common for ordinary work. In the construction of the Mississippi jetties, the block concrete was made with the following proportion: Portland cement, 1, sand 2½, clean gravel 1½, broken stone 5; the resulting mass was about 1½ yds. of concrete per yd. of broken stone. Common lime may be added to cement to increase the bulk of the "cement" paste, and consequently of the mortar, where concrete is not to be placed under water and where it is not subjected to excessive stress; but as common lime has no hydraulic properties, its addition to cement in mortar is simply the addition of so much inert matter, like sand, when the concrete is deposited under water.

A common custom of late is to designate concrete by the proportion of cement to sand assuming that the volume of broken stone shall be twice that of the sand. Thus, 1 to 2 matrix would mean 1 cement, 2 sand, and 4 broken stone, or 1 : 2 : 4 mix; 1 to 2½ matrix, a 1 : 2½ : 5 mix, etc. This abbreviation, unless explained (which explanation would tend to nullify the advantage of abbreviation itself) is apt to lead to error. The proportion of broken stone to sand need not necessarily be in the ratio 2 : 1. In the case of broken limestone, where the crushed rock is graded, and also where gravel is used, especially with broken stone, the ratio may be, say, 2½ : 1, 2½ : 1, etc. In all large work the percentage of voids, and consequently the proportions, should be determined by experiment for the classes of materials used. See page 417, where the method of determining voids, etc., is given.

In Mixing by hand, the cement and sand are thoroughly mixed dry on a clean platform, enough water is added to make a stiff paste, the broken stone (wet and previously washed clean) is then spread over the mortar and the whole thoroughly mixed by shoveling into another pile, and re-shoveling as often as necessary.* Concrete should be mixed in small batches and placed immediately, as the cement may set appreciably within 30 to 40 minutes after water is applied, and all subsequent disturbance may tend to weaken the mass.

Placing, Spreading and Ramming are operations which should closely follow one another rapidly. The concrete may be delivered in barrows, cable buckets, carts or chutes, the last named being the cheapest under favorable conditions. Spreading consists in pushing over the top of each batch dumped, so as to present a fairly level bed for the next layer. The layers are usually specified to be from 6 to 9 ins. in thickness. Ramming compacts concrete from 5 to 25% and makes it stronger by bringing the ingredients more intimately together, so that crystallization takes place more firmly. Rammers are round wooden blocks or logs about 4 ft. long, ring-shod at the lower end and provided at the upper end with handles for one-man or two-man manipulation.

Ramming should bring the concrete to a rather firm state with a flush of water at the top, but should not continue for an undue length of time so as to weaken its setting. "Dry" concrete naturally requires more ramming than a "wet" mixture. Before depositing a new layer, the top of the preceding layer should be wetted, after allowing not less than 12 hrs. for it to set. Where a layer is not wholly completed at the end of a day's work, its edge should be left rough (not smooth) for the next day's joining. "Medium" concrete is between "dry" and "wet." The advantage of medium concrete is that it can be rammed better than "wet," while at the same time possessing some of the good qualities of the latter.

Subaqueous Concrete has seldom been deposited with entire satisfaction even in still water to any great depth, but in moderate depths this has been accomplished with quite favorable results. The essential principle in depositing concrete under water is to convey it properly through the water so that the mix will not be disturbed by "wash." Examinations by divers

* Some engineers and most builders prefer to spread the (wet) gravel and broken stone on the dry cement-sand mix before water is added.—See German Specifications, pages 442, 443.

have in many cases disclosed "streaky concrete," with cement, sand and matrix more or less separated by wash, owing to their different specific gravities and fineness. The result of this lack of homogeneity is a reduction of strength, hence great care should be taken to insure as little disturbance as possible in placing the material. Under no circumstances should concrete be dumped loosely into water and allowed to settle in place. The three principal methods most commonly used are:

- (1) Depositing through closed chutes or tubes.
- (2) Depositing by means of specially arranged buckets.
- (3) Depositing in sacks or in bags.

The first method, by chute, is seldom used. The tube may be of any section, gradually enlarging toward the bottom to avoid clogging of the concrete fed continuously at top of tube. The tube is suspended vertically with the lower end at the bottom, and is moved laterally as the concrete falls into place. The principal objection to this method is the washing which the concrete receives in its descent.

The second method, by buckets, has been used with greater or less success. One of the most recent uses of this method was in the construction of a 3000-ft. pier at Superior Entry, Wis., by the Government, in about 23 ft. of water.* The steel buckets (Fig. 10) about 4 ft. cubes, open at the top, were provided with canvas covers, quilted with strips of sheet lead, to fold over the concrete and prevent wash. The buckets when lowered were tripped by a latch. Mr. Clarence Coleman, Asst. Engr. in charge, states that the examinations of concrete lowered 23 ft. and raised again in

Fig. 10.

the bucket showed the concrete to be in good condition; and that discoloration of the water from cement was seldom noticed during the descent of the bucket.

The third method, by bags, has been used extensively in both this country and in Europe. Mr. W. M. Patton, in his "Treatise on Foundations,"† page 102, says: "Perhaps the best mode of depositing concrete under water is to fill open sacks or gunny sacks about two-thirds to three-fourths full of the concrete or mortar, and deposit these in place, arranging them in courses, where practicable, header and stretcher system, and ramming each course as laid; the bagging is close enough not to allow the cement to be washed out, but at the same time open enough to allow the whole mass to be united and to become as compact as concrete itself. The writer used

* See Vol. 8, Part 4, of Report of Chief of Engineers, U. S. A.

† Published by John Wiley & Sons, New York.

this method in the foundation of a pier over 100 feet high, and has also adopted this plan in other works of less magnitude, but never has the result been satisfactory when deposited under water in any other manner."

Sub-Foundations are prepared by dredging, if necessary, and driving piles and cutting them off near the river bottom. Before concrete is deposited, molds are constructed of timber and sunk in place to give form to the concrete pier. The inside faces of the molds are of course smoothly lined, the timber frames being outside. Long adjustable bolts or turn-buckle rods are convenient to use with collapsible sides, where the same molds are to be used over again. See Sec. 50, Foundations.

Cement Grout (either pure cement, or 1 cement and say 1 sand) may be injected into a quick-sand or gravel foundation bed to form a sub foundation. The grout is pumped into vertical iron pipes perforated with holes at the bottom to allow it to ooze through into the natural bed material. The pipes should extend downward through the soft material to bed rock or other firm sub-stratum.

German Specifications for Concrete.—The following is a digest of portions of the report of standing committee of the German Concrete Society as adopted by that Society and entitled "Specifications for Designing, Constructing and Testing Concrete Structures." These specifications were brought to the attention of *Eng. News* by L. S. Moisseiff, and published under date of Nov. 9, 1905.

I. General.—Specifications apply to concrete construction in general, and to use of Portland cement in particular. Concrete is termed "wet" or "dry;" shall be capable of being tamped to acquire the necessary density to develop the required resistance. **II. Planning and Designing.** **III. Construction.** (A) General. (B) Superintendence and workmen. (C) Building Materials and their Working. (a) Materials: Cement which fulfils the requirements of the standard specifications for Portland cement shall be used exclusively. Quick setting cement shall not be used for concrete except in special cases. (The setting of the concrete is affected by the temperature and moisture of the air and the temperature of the water used. High temperature accelerates setting; low temperature retards it. In the presence of water pressure the use of quick setting cement is frequently necessary.) "Sand" includes land-, river- and sea-sand, as well as broken or crushed products, from fine grains to 0.28 in. in diameter (includes granulated furnace slag of proper consistency). "Gravel," from 0.28 in. up. "Gravel-sand," the natural mixture from excavations or beds of streams. The sand, gravel and broken stone shall be suitable (loam, clay and similar admixtures have an injurious effect if they adhere to the sand and stone; but if they are finely distributed in the sand, without adhering to the grains, they are, as a rule, harmless and may even sometimes increase the resistance), and shall not contain vegetable matter or other impurities. (The stone or gravel used shall, as a rule, have at least the same resistance as the hardened mortar. Stone not weather-resisting, soft sandstone, underburnt brick shall not be used for concrete. Slag is variable and should be tested). According to the thickness of the concrete body, gravel up to 2 ins. in dia. may be used. (Clean stones of large size of good compressive resistances and weathering qualities may be embedded in the concrete up to 40% of the total volume if the character and dimensions of the member allow it and provision be made for the proper distribution of such stones in the concrete as well as for the use of a sufficiently wet concrete to surround them completely.) For "broken stone," only hard rocks, unaffected by the weather, shall be used. As a rule, the broken stone shall also be of different sizes of stones as the concrete mass can then be worked easier and better, and gives a denser and stronger concrete. The sizes of the stones vary with the thickness of the concrete mass. The largest stones shall, according to their use, pass in any direction through a ring of 2.4 to 2.8 ins. diameter, or through a square of 2 to 2.4 on a side. Particles of sizes smaller than 0.28 in. down to stone dust shall be considered as sand. The "water" used shall be clean, etc. Marshy water is injurious. (b) Preparing the concrete: In proportioning the materials, if the cement be measured by volume it is understood that it is emptied into the measuring vessel without dropping and the latter is not shaken. To convert volumes into weights, a cubic foot of Portland cement shall be taken as 87.5 lbs. Gravel-sand and mixed broken stone may in many cases be used without being separated. Tests shall then be made by sieving to determine the proportions of the sand in the gravel or the stone dust in

"Mixing by hand" shall be in a proper mixing box. The sand shall first be mixed dry with the cement to a uniform color, then only shall the previously wetted gravel or stones, together with the water added to it, shall be mixed until a uniformly wet mass is produced. "Mixing by machine" shall be superior to hand-mixing. The time required varies with the machine and the character and quantity of the mix. The mixing shall be continued for 1 to 2 minutes, and the mixing is then continued until a thoroughly mixed, uniformly wet mass is produced. Generally, the mixing is complete when the stones are thoroughly wet with the mortar. The "quantity of water" to be added to a "dry" or "wet" mix is required, the character of the stones, moisture, and absorptive capacity. (More water is required in hot weather. When laying concrete in wet excavations, the quantity of water will have to be reduced, while a porous, absorbent material shall be wetted before laying the concrete.) When making concrete, enough water should be added that the concrete can be worked into a ball by the closing of the hand, leaving moisture on the surface. Making "wet" concrete the proportion of water shall be such as to make the concrete wet during the tamping. (c) The concrete shall be laid in place (excavation or foundation) and in such depths that the thickness of the completed concrete shall not, as a rule, exceed the following amounts: for concrete according to the stress, 6 to 8 ins.; for "wet" concrete, 8 to 12 ins. The individual layers shall be laid, at right angles to the direction of pressure, and where possible the layers shall be laid parallel with the direction of the pressure. The pressure insures a uniform concrete in the whole section, and is to be desired primarily where it is impracticable or where the quality of the tamping would suffer, as for instance in a flat arch, care shall be taken that the tamping shall not tend to displace the individual layers.) The concrete, as a rule, be laid on fresh concrete to obtain a sufficiently smooth surfaces after tamping shall be roughened; and the face shall be roughened by sweeping with steel brooms. The concrete, rich in stone, spread on a thin layer of wet mortar. For rectangular, 4 to 6½ ins. on a side and 22 to 27 lbs. per cu. yd. The "amount of tamping" required depends on the character of the concrete, "dry" or "wet" concrete requires more effort in tamping and greater care, but it generally produces for the same amount of concrete less distance than the "wet" concrete. Wet concrete may be injured by separation of the ingredients. Concrete shall be protected from "freezing weather" if the injurious effect of freezing weather means. Frozen materials shall not be used.

IV. REINFORCED CONCRETE.

Concrete is now used in various classes of construction and is a partial list: Abutments, aqueducts, arches, bins, etc.), bridges, buildings (foundations, walls, columns, piers, girders, retaining walls, sewers, sidewalks (supported), standpipes, ties (railroad), tunnels, etc., etc. The cheapening of concrete manufacture, due to the improved rotary kiln, the recent types of machines for preparing broken stone and the low cost of manufacture of the simple forms of steel used, with which the materials may be fabricated at the site, and the labor, are factors which have entered largely into the recent rapid development of this class of construction, in competition with what are ordinarily known as steel constructions. The added strength due to the steel reinforcement, a more scientific and economical distribution of material, the competition in many structures formerly built of plain masonry, as bridges, building walls, retaining walls, etc., and its merits are its preservative- and fire-resisting qualities, and its practically permanent construction.

The Preservative Qualities of Cement, with regard to iron or steel imbedded in the concrete, are pretty clearly established. Iron exposed to pure, dry air, or in moist air free from carbonic oxide, and at ordinary temperatures, will not rust. Rust is formed through the combined agency of carbonic acid and moisture, and as carbonic acid has a greater affinity for the cement mortar, the iron will not be attacked while the former is present, and encases it in a thorough manner. The few isolated cases recorded where rust has been found must be explained on the theory of some defect in workmanship or materials, as they stand out in marked contrast with practically all the accepted results of investigation on this subject. Perhaps the most notable instance of what may indirectly be called a long-time test was the finding of a small piece of "bright" iron in mortar taken from the base of the Egyptian obelisk (of granite, 70 ft. long, weighing 200 tons,) re-erected in Central Park, New York City, 1881. Numerous instances may be cited of iron being found in perfect condition after from 10 to 25 years' service in mortar or concrete (both stone and cinder) entering into various kinds of construction, both in and out of water (salt and fresh). To insure absolute protection, the bright rods may be coated with fresh cement when placed; and it is well to remember that they should be embedded thoroughly in the concrete, the latter to be a wet mixture, or a medium, well rammed, (the former preferred) to guard against voids.

The Fire-Resisting Qualities of Concrete and concrete-steel construction in buildings were illustrated in the Baltimore fire, in 1904. Although no construction was found to be really fireproof, it was noticeable that concrete made from steam-boiler cinders and Portland cement seemed to act the best; and that stone concrete stood fully as well as, if not better than, terra cotta. Results of other tests, specially made for comparison, point to the same conclusion. We may safely say, then, that reinforced concrete has all the fire-resisting qualities which may be expected in the best materials of construction of the present day.

The Proportions used in mixing concrete for reinforced-concrete construction almost invariably range from 1 cement, 2 sand, and 4 broken stone or gravel or cinders, to a 1 : 3 : 6 mix. Portland cement should be used. Clean, sharp sand is usually specified, but some engineers claim that sand well worn and rounded is best, and also cheapest as the voids are less, requiring less cement. A 1 : 3 : 6 mix is suitable for column- and wall construction; a 1 : 2½ : 5 mix, for girders; and a 1 : 2 : 4 mix for the lighter construction as floor slabs and small, shallow beams subject to direct impact from live load. The broken stone is also graded, say, from ½ in. upward to conform somewhat with the above proportions, the finer stone being used with the 1 : 2 : 4 mix, for the thinner masses.

Calculation of Beams.—The following analysis assumes that the resisting moment of the beam is made up of two moments: (1) that above the neutral axis, due to the concrete area in compression; and (2) that below the neutral axis, due to the steel area in tension, no account being taken of the concrete in tension. This is in accordance with the best practice at the present time.

Notation.

Let h = height of beam, in ins. (Fig. 11);

b = breadth of beam, in ins.;

$X-X$ = neutral axis;

d = depth to center of reinforcement, below top of beam, in ins.;

$h-d$ = distance from bottom of beam to center of reinforcement, in ins. (either d or $h-d$ may be fixed arbitrarily);

f = allowable compressive stress in lbs. per sq. in. on concrete to be used with the straight-line equivalent (instead of the stress f_0 due to the actual stress-strain diagram—shaded):

* f_2 mos. = 720 lbs. per sq. in. for good 1 : 2 : 4 concrete.

* f_2 mos. = 660 " " " " " " 1 : 2½ : 5 "

* f_2 mos. = 600 " " " " " " 1 : 3 : 6 "

Factor
safety = 4.

* These values are about 10% greater than the values of f_0 which would be used with the exact stress-strain curve.

Fig. 11.

F —allowable tensile stress in lbs. per sq. in. on the steel rods
(15000 for buildings);

a —sectional area of the steel rods, in sq. ins.;

k —ratio of moduli of elasticity of steel and concrete:

$k=13$ for steel and good 1 : 2 : 4 concrete.

$k=14$ " " " " 1 : 2½ : 5 " "

$k=15$ " " " " 1 : 3 : 6 " "

y —distance, in ins., from top of beam to neutral axis.

M^s —bending moment—resisting moment, inch-lbs.

M^r — " " " " " " ft.-lbs.

General Formulas:

Resisting moment, $M^s = \frac{1}{2} f b y^2 + a F (d - y)$ (1)

For conditions of equilibrium, the algebraic sum of the horizontal forces at any section must equal zero ($\Sigma H = 0$), hence we have, neglecting the tension in concrete, below the neutral axis, $a F = \frac{1}{2} f b y$ (2)

From the ratio k of the moduli of elasticity of the materials, and the relative position of the neutral axis, we have, $k f (d - y) = F y \therefore y = d \frac{k f}{F + k f}$ (3)

Combining (2) and (3), we have:

$$\text{Distance to neutral axis, } y = \frac{ak}{b} \left(\sqrt{1 + \frac{2bd}{ak}} - 1 \right) \dots\dots\dots (4)$$

$$\text{Breadth of beam, } b = \frac{2ak}{y^2} (d - y) \dots\dots\dots (4a)$$

$$\text{Area of steel rods, } a = \frac{by^2}{2k(d - y)} \dots\dots\dots (4b)$$

$$\text{Also, from (2), } a = y \frac{fb}{2F} \dots\dots\dots (4c)$$

$$\text{Depth to center of rods, } d = y \left(1 + \frac{by}{2ak} \right) \dots\dots\dots (4d)$$

Combining (1) and (2) we have:

$$\text{Stress in the concrete, } f = \frac{6 M^s}{by(3d - y)} \text{ lbs. per sq. in.} \dots\dots\dots (5)$$

$$\text{Stress in the steel,} \dots\dots F = \frac{3 M^s}{a(3d - y)} \text{ " " " " } \dots\dots\dots (6)$$

$$\text{Also, from (2), } F = \frac{fby}{2a} \text{ " " " " } \dots\dots\dots (6a)$$

The following values of ft may be assumed for the three standard concrete mixes: (See Table 4, next page.)

Concrete Mix.	Time.	Ultimate.	Factor 4.	Factor 5.	Factor 6.
1 : 2 : 4	1 mo.	$f = 2400$.	$f = 600$.	$f = 480$.	$f = 400$.
"	2 mos.	2880.	720.	576.	480.
"	3 mos.	3000.	750.	600.	500.
"	6 mos.	3600.	900.	720.	600.
1 : 2½ : 5	1 mo.	2200.	550.	440.	367.
"	2 mos.	2640.	660.	528.	440.
"	3 mos.	2750.	688.	550.	458.
"	6 mos.	3300.	825.	660.	550.
1 : 3 : 6	1 mo.	2000.	500.	400.	333.
"	2 mos.	2400.	600.	480.	400.
"	3 mos.	2500.	625.	500.	417.
"	6 mos.	3000.	750.	600.	500.

* Equation (3) gives y when a is unknown; it is directly proportional to d .

† For use with straight-line formulas adopted above. The values of f_c , or actual maximum compression on the outer element of the concrete, will be about 9% less.

4.—PROPERTIES OF REIN.-CONC. BEAMS 1" WIDE ($b=1$) AND OF VARIOUS DEPTHS, d OR h . (Fig. 11, page 444.)

Data: Concrete, 1 : 3 : 6; age, 2 mos.; $f=600$. Steel, $F=15000$. $k=15$. Factor of safety, 4. For factor of 5, mult. M' of table by $\frac{5}{4}$; for 6, by $\frac{3}{2}$.

24	4725.	9.00	.18	"	26.45	.0068	27.55

Formulas for above table, reduced from General Formulas, preceding, are: $y = \frac{1}{3}d$; $a = .02 \times \frac{1}{3}y = .0075d$; $M' = 8.203 d^3$. These values will vary, of course, with variations in the values of f , F , and k .

Suggested Formulas for Reinforced Concrete Construction (From Majority Report of Special Committee of Am. Soc. C. E. on Concrete and Reinforced Concrete. Proc. Am. Soc. C. E., Feb., 1909).—These formulas are based upon the assumptions and principles given in the chapter on Design (see Trans. A. S. C. E., Vol. LXVI). For WORKING STRESSES, see: Sec. 31, Beams, page 585; Sec. 32, Columns, page 609.

A. STANDARD NOTATION.

a. Rectangular Beams.

- f . = tensile unit stress in steel.
- f_c . = compressive unit stress in concrete.
- E_s . = modulus of elasticity of steel.
- E_c . = modulus of elasticity of concrete.
- $n = E_s \div E_c$.
- M = moment of resistance, or bending moment in general.
- A = steel area.
- b = breadth of beam.
- d = depth of beam to center of steel.
- k = ratio of depth of neutral axis to effective depth, d .
- z = depth of resultant compression below top.
- j = ratio of lever arm of resisting couple to depth, d .
- $jd = d - z$ = arm of resisting couple.
- p = steel ratio (not percentage).

I-Beams.

- b = width of flange.
- b' = width of stem.
- t = thickness of flange.

Beams Reinforced for Compression.

- A' = area of compressive steel.
 ρ' = steel ratio for compressive steel.
 f'_s = unit compressive stress in steel.
 C = total compressive stress in concrete.
 C' = total compressive stress in steel.
 d' = depth to center of compressive steel.
 z = depth to resultant of C and C' .

Shear and Bond.

- V = total shear.
 v = shearing unit stress.
 u = bond stress per unit area of bar.
 o = circumference or perimeter of bar.
 Σo = sum of the perimeters of all bars.

Columns.

- A = total net area.
 A_s = area of longitudinal steel.
 A_c = area of concrete.
 P = total safe load.

B. FORMULAS.
a. Rectangular Beams.

Fig. 12.

Position of neutral axis,

$$k = \sqrt{2pn + (pn)^2} - pn.$$

 Arm of resisting couple, $j = 1 - \frac{1}{3}k.$

 For $f_c = 15\,000$ to $16\,000$ and $f_t = 600$ to 650 , j may be taken at $\frac{7}{8}$.

$$\text{Fiber stresses, } f_t = \frac{M}{Ajd} = \frac{M}{\rho j b d^2}, \quad f_c = \frac{2M}{j k b d^2} = \frac{2\rho f_t}{k}.$$

$$\text{Steel ratio, } \rho = \frac{1}{2} \frac{f_c}{f_t} \left(\frac{f_t}{\rho f_t} + 1 \right).$$

b. T-Beams.

Fig. 13.

Case I. When the neutral axis lies in the flange, use the formulas for rectangular beams.

Case II. When the neutral axis lies in the stem.

The following formulas neglect the compression in the stem:

Position of neutral axis,

$$kd = \frac{2ndA + bt^2}{2nA + 2bt}.$$

Position of resultant compression,

$$s = \frac{3kd - 2t}{2kd - t} \cdot \frac{t}{3}.$$

Arm of resisting couple,

$$jd = d - s.$$

Fiber stresses,

$$f_s = \frac{M}{Ajd}, \quad f_c = \frac{Mkd}{bt(kd - \frac{1}{3}t)jd} = \frac{f_s}{n} \cdot \frac{k}{k-1}.$$

(For approximate results, the formulas for rectangular beams may be used.)

The following formulas take into account the compression in the stem; they are recommended where the flange is small compared with the stem.

Position of neutral axis,

$$kd = \sqrt{\frac{2ndA + (b-b')t^2}{b'} + \left(\frac{nA + (b-b')t}{b'}\right)^2} - \frac{nA + (b-b')t}{b'}.$$

Position of resultant compression,

$$s = \frac{(kdt^2 - \frac{1}{3}t^3)b + [(kd-t)^2(t + \frac{1}{3})(kd-t)]b'}{t(2kd-t)b + (kd-t)^2b'}.$$

Arm of resisting couple,

$$jd = d - s.$$

Fiber stresses,

$$f_s = \frac{M}{Ajd}, \quad f_c = \frac{2Mkd}{[(2kd-t)bt + (kd-t)^2b']jd}.$$

c. Beams Reinforced for Compression.

Fig. 14.

Position of neutral axis,

$$k = \sqrt{2n \left(p + p' \frac{d'}{d} \right) + n^2 (p + p')^2} - n(p + p').$$

Position of resultant compression,

$$s = \frac{\frac{1}{3}k^2d + 2p'nd' \left(k - \frac{d'}{d} \right)}{k^2 + 2p'n \left(k - \frac{d'}{d} \right)}.$$

Arm of resisting couple,

$$jd = d - s.$$

Fiber stresses

$$f_s = \frac{6Mk}{bd^2 \left[3k - k^2 + \frac{6p'n}{k} \left(k - \frac{d'}{d} \right) \left(1 - \frac{d'}{d} \right) \right]}$$

$$f_s = \frac{M}{p_j b d^2} = n f_s \frac{1-k}{k}$$

$$f_s' = n f_s \frac{k - \frac{d'}{d}}{k}$$

d. Shear, Bond, and Web Reinforcement.

In the following formula, Σ_0 refers only to the bars constituting the tension reinforcement at the section in question and $j d$ is the lever arm of the resisting couple at the section.

For rectangular beams,

$$v = \frac{V}{b j d}$$

$$u = \frac{V}{j d \cdot \Sigma_0}$$

[For approximate results, j may be taken at $\frac{7}{8}$.]

The stresses in web reinforcement may be estimated by using the following formulas:

Vertical reinforcement,

$$P = \frac{Vs}{j d}$$

Reinforcement inclined at 75° ,

$$P = 0.7 \frac{Vs}{j d}$$

in which P = stress in single reinforcing member, V = proportion of total shear assumed as carried by the reinforcement, and s = horizontal spacing of the reinforcing members.

The same formulas apply to beams reinforced for compression as regards shear and bond stress for tensile steel.

For T-beams,

$$v = \frac{V}{b' j d}, \quad u = \frac{V}{j d \cdot \Sigma_0}$$

[For approximate results, j may be taken at $\frac{7}{8}$.]

e. Columns.

Total safe load,

$$P = f_s (A_s + n A_c) = f_s A (1 + (n-1)p)$$

Unit stresses,

$$f_s = \frac{P}{A (1 + (n-1)p)}$$

$$f_s = n f_c$$

V. MIXED MASONRY.

The object of using mixed masonry is to give a substantial looking, finished face, using a better class of masonry for this purpose, and using a cheaper quality for interior and back of wall. Strictly speaking, most masonry is more or less mixed—ashlar backed with rubble, face-brick backed with common brick, etc.; but the term "mixed masonry" is generally restricted to stone facing with brick backing.

The bond between stone and brick, or stone and concrete, is often a source of weakness. When interior brick walls are joined to stone face-walls, iron "cramps" are generally employed.

VI.—CONCRETE-BLOCK MASONRY.

Solid concrete blocks are often used in submarine work, as for breakwater construction, in preference to laying the concrete in situ.

Hollow concrete blocks are made in many shapes and are used in construction. The completed wall should generally be not two-thirds solid, although in some places as much as 40- to 50 per cent voids is allowed. The surface of the blocks should be rich in cement and have a finer aggregate than the interior. The best blocks are made by machine under heavy (usually hydraulic) pressure. The writer has seen many blocks turned out by the small, portable machines in which tamping is required, and the results were invariably inferior. They are laid in the wall in cement mortar, and sometimes iron cramps are used for bonding them together. Outside cement plaster or stucco of good quality may be laid directly on the blocks, and gives a finished appearance. Inside plaster should not be laid without furring and lathing, if the blocks are porous or inferior in quality on account of moisture and frost. The blocks have been waterproofed.

Specifications for Hollow Concrete Building Blocks.—The following are from the Rules and Regulations governing the use and manufacture of Hollow Concrete Building Blocks in the City of Philadelphia—Building Inspection.

Rules and Regulations.

1. Hollow concrete building blocks may be used for building walls of less than 12 in. in height, where said use is approved by the Bureau of Building Inspection; provided, however, that such blocks shall be composed of at least 1 part standard Portland cement, and not to exceed 5 parts of coarse, sharp sand or gravel, or a mixture of at least 1 part Portland cement to 5 parts crushed rock or other suitable aggregate. Provided that this section shall not permit the use of hollow blocks in party walls. Said party walls must be built solid.

2. All material to be of such fineness as to pass a $\frac{1}{2}$ -in. ring and free from dirt or foreign matter. The material composing such blocks shall be properly mixed and manipulated, and the hollow space in such blocks shall not exceed the percentage given in the following table for walls of different heights, and in no case shall the walls or webs of the blocks be less than $\frac{1}{4}$ of the height. The figures given in the table represent the percentage of such hollow space for different heights.

Stories.	1st.	2nd.	3rd.	4th.	5th.	6th.
1 and 2....	33	33				
3 and 4....	25	33	33	33		
5 and 6...	20	25	25	33	33	33

3. The thickness of walls for any building where hollow concrete blocks are used shall not be less than is required by law for brick walls.

4. Where the face only is of hollow concrete building blocks, the backing is of brick, the facing of hollow concrete blocks must be bonded to the brick either with headers projecting 4 ins. into the brick work, every fourth course being a heading course, or with approved no brick backing to be less than 8 ins. Where the walls are made of hollow concrete blocks, but where said blocks have not the same bond as the wall, every fifth course shall extend through the wall, to form a secure bond. All walls, where blocks are used, shall be laid up in cement mortar.

5. All hollow concrete building blocks, before being used in the construction of any building in the City of Philadelphia, shall have been in the age of at least 3 weeks.

6. Wherever girders or joists rest upon walls so that there is a concentrated load on the block of over 2 tons, the blocks supporting the joists must be made solid. Where such concentrated load shall exceed 2 tons, the blocks for 2 courses below, and for a distance extending 18 ins. each side of said girder, shall be made solid. Where the load on the wall from the girder exceeds 5 tons, the blocks for 3 courses beneath the load must be made solid with similar material as in the blocks. Where the wall is decreased in thickness, the top course of the thicker wall to be

7. Provided always, that no wall, or any part thereof, composed of hollow concrete blocks shall be loaded to an excess of 8 tons per superficial foot of the area of such blocks, including the weight of the wall, and no blocks shall be used that have an average crushing at less than 1000 pounds per square inch of area at the age of 28 days; no deduction to be made in figuring the area for the hollow spaces.

8. All piers and buttresses that support loads in excess of 5 tons, shall be built of solid concrete blocks for such distance below as may be required by the Bureau of Building Inspection. Concrete lintels and sills shall be reinforced by iron or steel rods in a manner satisfactory to the Bureau of Building Inspection, and any lintels spanning over 4 feet six inches in the clear shall rest on solid concrete blocks.

9. Provided, that no hollow concrete building blocks shall be used in the construction of any building in the City of Philadelphia, unless the maker of said blocks has submitted his product to the full test required by the Bureau of Building Inspection, and placed on file with said B. of B. I. a certificate from a reliable testing laboratory showing that samples from the lot of blocks to be used have successfully passed the requirements of the B. of B. I., and filing a full copy of the test with the Bureau.

10. A brand or mark of identification must be impressed in, or otherwise permanently attached to, each block for purpose of identification.

11. No certificate of approval shall be considered in force for more than four months, unless there be filed with the B. of B. I., in the City of Phila., at least once every four months following, a certificate from some reliable physical testing laboratory showing that the average of three (3) specimens tested for compression, and three (3) specimens tested for transverse strength, comply with the requirements of the B. of B. I.; samples to be selected either by a Building Inspector or by the laboratory, from blocks actually going into construction work. Samples must not be furnished by the contractors or builders.

12. The manufacturer and user of any such hollow concrete blocks as are mentioned in this regulation, or either of them, shall, at any and all times, have made such tests of the cements used in making such blocks, or such further tests of the completed blocks, or of each of these, at their own expense, and under the supervision of the B. of B. I., as the Chief of said Bureau shall require.

13. The cement used in making said blocks shall be Portland cement, and must be capable of passing the minimum requirements as set forth in the "Standard Specifications for Cement" by the American Society for Testing Materials.

14. Any and all blocks, samples of which, on being tested under the direction of the B. of B. I., fail to stand at 28 days the tests required by this regulation, shall be marked "condemned" by the manufacturer or user, and shall be destroyed.

15. No concrete blocks shall be used in the construction of any building within the City of Phila. until they shall have been inspected, and average samples of the lot tested, approved and accepted by the Chief of Building Inspectors.

Method of Testing Hollow Blocks.

1. These regulations shall apply to all such new materials as are used in building construction, in the same manner and for the same purposes as stones, brick, concrete are now authorized by the Building Laws, when said new material to be substituted departs from the general shape and dimensions of ordinary building brick, and more particularly to that form of building material known as "Hollow Concrete Block," manufactured from cement and a certain addition of sand, crushed stone, or similar material.

2. Before any such material is used in buildings, an application for its use and for a test of the same must be filed with the Chief of the B. of B. I. A description of the material and a brief outline of its manufacture and proportions of the materials used must be embodied in the application.

3. The material must be subjected to the following tests: Transverse, Compression, Absorption, Freezing, and Fire. Additional tests may be called for when, in the judgment of the Chief of the B. of B. I., the same

may be necessary. All such tests must be made in some laboratory of recognized standing, under the supervision of the Engineer of the B. of B. I. The tests will be made at the expense of the applicant.

4. The results of the tests, whether satisfactory or not, must be placed on file in the B. of B. I. They shall be open to inspection upon application to the Chief of the Bureau, but need not necessarily be published.

5. For the purposes of the tests, at least 20 samples of test pieces must be provided. Such samples must represent the ordinary commercial product. They may be selected from stock by the Chief of the B. of B. I., or his representative, or may be made in his presence, at his discretion. The samples must be of the regular size and shape used in construction. In cases where the material is made and used in special shapes and forms, too large for testing in the ordinary machines, smaller sized specimens shall be used as may be directed by the Chief of Building Inspection, to determine the physical characteristic specified in Section 3.

6. The samples may be tested as soon as desired by the applicant, but in no case later than 60 days after manufacture.

7. The weight per cubic foot of the material must be determined.

8. Tests shall be made in series of at least five, except that in the fire tests a series of two (four samples) are sufficient. Transverse tests shall be made on full sized samples. Half samples may be used for the crushing, freezing, and fire tests. The remaining samples are kept in reserve, in case unusual flaws or exceptional or abnormal conditions make it necessary to discard certain of the tests. All samples must be marked for identification and comparison.

9. The Transverse test shall be made as follows: The samples shall be placed flatwise on two rounded knife edge bearings set parallel seven inches apart. A load is then applied on top, midway between the supports, and transmitted through a similar rounded knife edge, until the sample is ruptured. The modulus of rupture shall then be determined by multiplying the total breaking load in pounds by twenty-one (three times the distance between supports in inches) and then dividing the result thus obtained by twice the product of the width in inches by the square of the depth in inches: $R = \frac{3 w l}{2 b d^2}$. No allowance should be made in figuring the modulus of rupture for the hollow spaces.

10. The Compression test shall be made as follows: Samples must be cut from blocks so as to contain a full web section. The sample must be carefully measured, then bedded flat-wise in Plaster of Paris, to secure a uniform bearing in the testing machine, and crushed. The total breaking load is then divided by the area in compression in square inches. No deduction to be made for hollow spaces; the area will be considered as the product of the width by the length.

11. The Absorption test must be made as follows: The sample is first thoroughly dried to a constant weight. The weight must be carefully recorded. It is then placed in a pan or tray of water, face downward, immersing it to a depth of not more than one-half inch. It is again carefully weighed at the following periods: Thirty minutes, four hours, and forty-eight hours, respectively, from the time of immersion, being replaced in the water in each case as soon as the weight is taken. Its compressive strength, while still wet, is then determined at the end of the forty-eight hours' period, in the manner specified in section 10.

12. The Freezing test is made as follows: The sample is immersed, as described in section 11, for at least four hours, and then weighed. It is then placed in a freezing mixture or a refrigerator, or otherwise subjected to a temperature of less than 15 degrees F. for at least 12 hours. It is then removed and placed in water, where it must remain for at least one hour, the temperature of which is at least 150 degrees F. This operation is repeated ten (10) times, after which the sample is again weighed while still wet from the last thawing. Its crushing strength should then be determined as called for in section 10.

13. The Fire test must be made as follows:—Two samples are placed in a cold furnace in which the temperature is gradually raised to 1700 degrees F. The test piece must be subjected to this temperature for at least 30 minutes. One of the samples is then plunged in cold water (about 50

degrees to 60 degrees F.) and the results noted. The second sample is permitted to cool gradually in air, and the results noted.

14. The following requirements must be met to secure the acceptance of the materials: The Modulus of Rupture for concrete blocks at 28 days old must average 150 and must not fall below 100 in any case. The ultimate compressive strength at 28 days must average 1000 lbs. per sq. in., and must not fall below 700 in any case. The percentage of absorption (being the weight of water absorbed divided by the weight of the dry sample), must not average higher than 15% and must not exceed 25% in any case. The reduction of compressive strength must not be more than 33½%, except that when the lower figure is still above 1000 lbs. per sq. in., the loss in strength may be neglected. The freezing and thawing process must not cause a loss in weight greater than 10%, nor a loss in strength of more than 33½%; except that when the lower figure is still above 1000 lbs. per sq. in., the loss in strength may be neglected. The fire test must cause the material to disintegrate.

15. The approval of any material is given only under the following conditions: *a.* A brand mark for identification must be impressed on, or otherwise attached to, the material. *b.* A plant for the production of the material must be in full operation when the official tests are made. *c.* The name of the firm or corporation and the responsible officers must be placed on file with the Chief of B. of B. I., and changes in same promptly reported. *d.* The chief of the B. of B. I. may require full tests to be repeated on samples selected from the open market when, in his opinion, there is any doubt as to whether the product is up to the standard of these regulations, and the manufacturer must submit to the B. of B. I., once in at least every 4 months, a certificate of tests showing that the average resistance of 3 specimens to cross breaking and crushing are not below the requirements of these regulations. Such tests must be made by some laboratory of recognized standing, on samples selected either by a Building Inspector or the laboratory, from material actually going into construction, and not on ones furnished by the manufacturer. *e.* In case the results of tests made under this condition (*d.*) should show that the standard of these regulations is not maintained, the approval of this bureau to the manufacturer of said blocks will at once be suspended or revoked.

EXCERPTS AND REFERENCES.

Permeability of Concrete Under High Water Pressures (By J. B. McIntyre and A. L. True. Thesis, Thayer School of Civ. Engr., April, 1902; Eng. News, June 26, 1902).—Extensive tables of tests, using different proportions of concrete, and pressures of 20, 40, and 80 lbs., time 2 hours. "Of the various mixtures we may safely choose either 1:2:4 or 1:2.5:4, on account of their simplicity and the ease with which they may be proportioned, either for hand or machine mixing. In extreme cases however, it might be advisable to use one of the richer mixtures."

Notes on Concrete Construction in Government Fortifications—With Waterproofing Data (Report of Chief of Engrs. of U. S. A. for 1902; Eng. News, April 2, 1903).—Subjects treated are: "Tests to show suitability of various kinds of sand for use in concrete," by Capt. Harry Taylor; "Damp proofings for ceilings of gun emplacements," by Maj. G. W. Goethals; "Damp proofing sunken magazines and rooms," by Col. P. C. Hains; "Stoppage of leaks in concrete with linseed oil," by Capt. E. W. Van C. Lucas; "Stoppage of leaks in concrete with asphaltum and oil," by Maj. W. T. Rossell and Capt. S. Crosby; "Asphaltum and alum and lye waterproofing," by Capt. W. C. Langfitt; "A sliding rupture caused by tarred paper waterproofing," by Maj. W. T. Rossell and Capt. S. Crosby.

The Efficiency of Concrete-Mixing Machines (By Clarence Coleman. Eng. News, Aug. 27, 1903).—**The Necessity of Thorough Mixing.**—The amount of cement as determined for any concrete should always be weighed, not measured, as the volume of cement is a variable. The entire amount of cement should be added before mixing is commenced, and then mixed dry before water is added. The proper amount of water to be added requires judgment after visual inspection, as the hygrometric condition of the sand is a variable; hence the entire mass of the materials should be plainly visible to the person adding the water. **Proportion of Water in**

Concrete.—Gives a table showing the strength of mortar due to varying proportions of water. **Classification of Machines.**—Batch Mixers (7 types described); Continuous Mixers (5 types described). **Comparison of Concrete Mixers.**—Descriptions with illustrations.

The Method of Finishing the Concrete Surfaces of Philadelphia Bridges (By H. H. Quimby. Eng. News, Feb. 4, 1904).—Remove the forms while the concrete is still "green," and simply wash the surface with water, squirting it on with a nozzle if the work is soft enough, or, if harder, using a scrubbing brush. If the cement is too hard to wash off it must be cut by hard rubbing with a brick or a wooden float and sand, using plenty of water. The removal of the cement exposes the sand and grit or pebbles or stone—whatever the aggregate may be—leaving a surface that is mostly stone, and is probably as little subject to discoloration and cracks as stone, and as durable as any plastic material can be made.

Tests of Adhesion and Initial Stress of Steel in Concrete (By S. W. Emerson. Eng. News, Mar. 10, 1904).—Diagrams showing results of tests.

Materials Required to Make Different Classes of Concrete for Connecticut Ave. Bridge, Wash., D. C. (By W. J. Douglas and A. W. Dow. Eng. News, Mar. 10, 1904).—

Class.....	A.	B.	B.	C.
Mixture (cem., sand, gravel, stone).....	1:2:0:4½	1:2½:0:6	1:2½:3:3	1:3:10:0
Cement, cu. ft.....	4.5	4.5	4.5	4.5
Sand, cu. ft.....	9.0	11.25	11.25	13.5
Gravel, cu. ft.....	0.0	0.0	18.5	45.0
Broken Stone, cu. ft.....	20.25	27.0	13.5	0.0
Yielded, rammed concrete, cu. ft.....	21.4	27.66	27.66	45.0

Note that 4.5 cu. ft. (Vulcanite) cement = 1 bbl. = 4 bags = 378.25 lbs.

French Government. Rules for the Design and Construction of Reinforced Concrete (Eng. News, Mar. 21, 1907).—Discussion of formulas, etc.

Expansion Joints in Concrete Structures, with Special Reference to Block Construction in Drydocks and Reservoirs (L. F. Bellinger. Eng. News, May 2, 1897).—Brightwood Reservoir, Wash., D. C.—Dimensions, 415 x 300 x 20 ft. deep; plain concrete with a vertical outer face and a sloping inner face of concrete; the vertical outer face having a heavy earth embankment against it. The concrete wall was built in alternate sections not exceeding 50 ft. long. Vertical key ways 6 ins. square, ½ of which was in each section, were built for expansion joints and first filled with asphalt. The concrete proportions were 1:2½:5. In placing the fresh concrete on that which was already set, the surface was carefully washed and rich mortar was placed in order to make a joint. The forms were left on from one to two days to harden; surfaces which were to be exposed to the air or water had a face of 1:2 mortar, 6 ins. thick, placed at the same time the concrete backing was placed. The concrete floor was laid in two layers, each 5 ins. thick, and laid in blocks 15 ft. square. In the joints was placed a 3-ply felt, up to bevels, which topped off each joint. After the shrinkage cracks appeared, these bevels were run full of asphalt and then 2 ins. of 1:2 mortar was troweled over everything. The experience with this reservoir is interesting since the asphalt in the key ways cracked and leaked in cold weather, and in warm weather ran out beneath the water surface. The asphalt was finally taken out and replaced with carefully selected puddling clay and rammed into the key ways. The contraction of the concrete permitted this material also to run out through the expansion joints into the reservoir and caused leaks to appear through the embankment. After this occurred, the puddling clay was taken out and plain loam, with clay, sand, grass roots, dirt and fibrous material, were rammed into the key ways. This material has successfully prevented leaks up to the present time. **Other Data.**—About a dozen other works described; also Expansion Joints in Drydocks (illus.); Block Construction; Key Ways, etc.

26.—STEREOTOMY.

This term in its broadest sense includes the subject of Stone Cutting (see page 426.), but it is here restricted to the preparation of the drawings and sketches of the dimension stones, which enter into the masonry structure, previously designed.

The drawings of the simpler shapes may be ordinary sketches in projection, showing the principal faces with dimensions thereon, or descriptions of same; but isometric views should be shown of the more complex shapes. The dimensions of the shapes may be obtained (1) by analytic calculation, (2) by projection and development, (3) by Descriptive Geometry. All these methods commonly enter into the case of a single structure. Only a few hints can be given here, but these, it is hoped, will serve to illustrate a more extended application.

Wall of Building.—Fig. 1 illustrates the simple method of showing the dimensions of stones on the Elevation plan. These dimensions are usually given on the drawing to center of joint with a note on plan to that effect, as

Fig. 1.

"Allow for $\frac{1}{4}$ " joints." The thickness of joint may vary from about $\frac{1}{8}$ " upward, depending upon the quality of the masonry; $\frac{1}{4}$ " is common for public buildings. In engineering structures $\frac{1}{8}$ " is about the minimum, and from that up to $\frac{1}{2}$ " for dimension work. Note that in Fig. 1 each stone is num-

Fig. 2.

bered. Fig. 2 is an isometric view of stone No. 63 (not shown in elevation) of the water-table. All the dimensions L , H , h , W and w should be placed directly on the drawing. L and H may be "finished dimensions" like the others, or they may be distances to center of joints. Proper notes should be made showing which system is used.

Stone Arch.—Fig. 3 illustrates, briefly, two methods of showing the dimensions of the voussoirs for the stone cutter. Those shown in the end view (face of arch) are in planes perp to axis of arch, whether for right- or skew arch. The measurements shown may be (1) to center of joints as per the "numbered" voussoirs, or (2) actual dimensions as per the "lettered" voussoirs (Fig. 3). Isometric views of stones "4" and "I" assume the arch to be skewed or oblique, with coursing joints parallel with axis of arch. (Such a construction is allowable only for slight skew, for small arches, or culverts. When the skew is considerable, especially for large spans, the

27.—WEIGHTS AND SPECIFIC GRAVITIES OF MATERIALS.

(For Strength and Resistance of Materials, see Sec. 28.)

DEFINITIONS.

Mass (M) = Matter.—If two separate quantities of matter will balance each other in vacuo they are said to have equal masses; and this regardless of kind of matter, volume, or temperature. The only stipulation is that they shall be affected by the same gravity acceleration g , and this necessarily obtains when they are counterpoised at the same time, at the same elevation above sea level, and at the same parallel of latitude or place.

Mass = $\frac{\text{weight}}{\text{gravity acceleration}}$; or $M = \frac{W}{g}$, the usual formula.

The "unit of mass" (M_1) may be a definite and standard quantity of matter. For instance, if a certain quantity of a particular metal occupies one cubic inch (C_1), and weighs one standard pound (W_1) at a point on the earth where the gravity acceleration (g_1) corresponding to W_1 , is equal to, say, 32.16,—then its mass (M) is equal to $\frac{W_1}{g_1} = \frac{1}{32.16}$ lb. Hence, the unit of mass (M_1) of the metal would be equal to 32.16 cubic inches, or 32.16 lbs. at that particular locality.

The "unit of mass" is equal to g pounds.

Gravity Acceleration (g).—The value of g increases with the latitude of the place, and decreases with the elevation above sea level. The following formula* gives the value of g for any latitude and elevation:

$$g = 32.172 - 0.082 \cos 2\lambda - 0.000003 h \dots \dots \dots (1)$$

where g = acceleration in ft. per sec. per sec.;

λ = latitude of the place in degrees;

h = elevation in feet above sea level.

From this formula the values of g and $\sqrt{g}$ (used in Hydraulics) are as follows, for various latitudes, at sea level:

Latitude	0°	10°	20°	30°	40°	45°
g	32.090	32.095	32.109	32.131	32.158	32.172
$\sqrt{2g}$	8.011	8.012	8.014	8.016	8.020	8.021

The value of g may be designated as the *intensity of gravity*.

Weight (W) = Mg .—The weight of a body depends upon its mass (M) and upon the intensity of gravity (g). If the mass is constant the weight will vary directly with g . From the preceding table we see that a mass weighing 32,131 lbs. in latitude 30°, would weigh 32,172 lbs. in latitude 45°; that is, the weight of the same mass would increase 41 lbs. in 15° of latitude, or a little more than 2½ lbs. per ton. This is so small as to be practically negligible in engineering calculations, and we generally assume for g its value in latitude 40°, namely, $g = 32.16$. It is to be noted, then, that the weights per cubic foot of substances given in the subjoined tables are practically constant, in so far as the intensity of gravity alone is concerned, in all portions of the country.

* In C. G. S. (Centimeter-Gram-Second) System, adopted by the British Association, the value of g in centimeters is sometimes given: $g = 980.6056 - 2.5028 \cos 2\lambda - .000003h$. See also formula for g under Simple Circular Pendulum Mechanics, page 287.

Volume (V).—The unit of volume generally used in the United States is the cubic foot, and weights are given in pounds per cubic foot. The effect of temperature upon any mass is to increase its volume (ice excepted); hence, in giving the weights of those substances which expand materially with heat, the temperature should be stated. This is true especially with gases and, to a much less extent, with liquids. But with ordinary materials of engineering the temperature effect on volume is so slight, within the natural range of the thermometer, as to be negligible.

The volume of any mass is inversely as its density; thus, $V = \frac{M}{D}$.

Then for any unit mass the volume and density are reciprocals of each other.

Density (D).—The density of any body is the mass of a unit of its volume; thus in the equation $M=VD$, if $V=1$, $M=D$. If, now, this unit mass is increased, say by temperature, to two units of volume, then will its density be equal to $\frac{1}{2}M$, or 50 per cent of what it was. If, on the other hand, the unit mass is decreased, say by pressure, to $\frac{2}{3}$ its original volume, then will its density be $1.25 M$.

The *relative density* of a substance is called its *specific gravity*, when referred to water (at maximum density—4° Centigrade).

Specific Gravity (s. g.).—The specific gravity of a substance is its relative density, to a unit standard. More definitely, it is the ratio of the weight of a given volume of the substance to the weight of the same volume of distilled water at 4°C (39.1 F.), its maximum density, equal to 62.424 pounds per cubic foot, and considered as unity. Moreover, the specific gravities of other substances than water are assumed to be taken at 0°C., or if not they are reduced by corrections to that temperature. These are the standards of physicists.

Experimenters, especially in the field of engineering, have not always reduced their results to the above standards, but have variously employed as standard units, uncorrected,

Water at		0° C. or	32° F.,	equal to	62.416 lbs. per cu. ft.
(	"	4° C.	39.1° F.	"	62.424 " " "
"	"	15.56° C.	60° F.	"	62.366 " " "
"	"	16° C.	60.8° F.	"	62.361 " " "
"	"	16.67° C.	62° F.	"	62.355 " " "

And for the substances experimented with, the temperatures, when stated, have been as varied as the above. Hence, in the subjoined tables of specific gravities, extreme accuracy cannot be expected in many cases, but they are sufficiently exact for all engineering purposes.

Specific gravity—weight in grams per cubic centimeter.

METHODS FOR DETERMINING SPECIFIC GRAVITY.

Solids Heavier than Water.—A common method for determining the specific gravity of a solid heavier than water is to weigh it *in air* and then weigh it *in water*; that is, while still in the scale it is immersed in water, where its weight will be found to be less. The specific gravity may then be expressed by the following formula, when temperature reduction is not considered:

$$\text{Specific gravity} = \frac{W}{W - w} \dots\dots\dots (2)$$

In which W = weight of the substance in air;
 w = " " " " when immersed in water;

$W - w =$ "loss of weight" by immersion.

Solids Lighter than Water may be determined by finding the weight (W) in air, as above, and then the buoyancy or minus weight (w') in water, when completely immersed. Formula (2) then reduced to (3), as follows:

$$\text{Specific gravity} = \frac{W}{W + w'} \dots\dots\dots (3)$$

In which $w' = -w =$ force required to immerse the body.

Displacement Method.—This consists in immersing the substance to be determined, in a vessel full of water. Hence,

$$\text{Specific gravity} = \frac{\text{weight of the substance}}{\text{weight of water displaced}} \dots\dots\dots (4)$$

Porous substances whose specific gravities are to be determined should be painted with a thin coat of varnish before being immersed, in order to exclude all moisture.

Granular substances may have two specific gravities, namely, *in bulk* and *in grains*. Substances which are affected by water should be weighed in some other liquid which will not affect them and whose specific gravity is known. Alcohol, turpentine and benzine are often used for this purpose. Then, the specific gravity obtained with respect to the particular liquid must be multiplied by the specific gravity of the liquid itself, to find the true specific gravity.

For determining the specific gravity of cement, see description of method, page 407, under Building Stones and Cements, Sec. 22.

Liquids.—The practical determination of the specific gravities of liquids may be made with instruments called *hydrometers*. They consist usually of a glass tube (or wire) so arranged that it will stand vertically when partly immersed in a liquid. The depth of immersion, registered by a *scale* on the tube, or the weight required to immerse the tube to a certain *fixed mark* upon it, with reference to the surface of the liquid in which it is immersed, is the basis on which the specific gravity is determined. "Scale" hydrometers are of variable immersion and constant weight; "fixed-mark" hydrometers are of constant immersion and variable weight. Some hydrometers are specially adapted to determining liquids *heavier* than water; and some to determine liquids *lighter* than water. Again, some hydrometers are immersed in the liquid whose specific gravity is to be determined; while others are immersed in a standard liquid, and are provided with a cup at the top of the tube to receive the liquid which is to be determined. Other forms of instruments, perhaps not strictly hydrometers, are used to determine the purity or adulteration of various liquids, as spirits, solutions, milk, urine, etc. The relative density to some standard of purity is the basis of the determination.

Fig. 1.

Beaumé's hydrometer, Fig. 1, is a "scale" hydrometer of variable immersion, which is immersed in the liquid to be determined. The graduation of the scale for liquids lighter than water is different than for those heavier than water. The graduation is standardized by the depth of immersion (1) in pure water for one point on the scale, and (2) in a saline solution of known strength for another point. The distance between the two points is then graduated, and the graduation extended beyond either point when necessary. The lower end of the tube is loaded with mercury, and a bulb is blown above it.

The following relations exist between Beaumé's Hydrometer scale and the corresponding *Specific Gravity* desired:

Beaumé (deg.).....	0	10	20	30	40	50	60
Liquid heavier than water.....	1.000	1.070	1.152	1.246	1.357	1.490	1.652
Liquid lighter than water.....		1.000	.936	.880	.830	.785	.745

Many hydrometers now record the specific gravities directly.

Tweddell's hydrometer is a scale hydrometer for determining liquids heavier than water. It is graduated in degrees D° such that

$$\text{Specific gravity} = \frac{5 D^{\circ} + 1000}{1000} \dots\dots\dots (5)$$

Rousseau's densimeter is for variable immersion in a standard liquid. It is constructed somewhat similar to Beaumé's (Fig. 1) but has in addition a tube or cup at the top of the stem which contains the liquid to be determined. Hence, it is specially adapted to determining specific gravities of small quantities of liquids.

* The specific gravity of a liquid may be obtained directly by weighing equal volumes of the liquid and of water, dividing the weight of the former by that of the latter.

Nicholson's and Fahrenheit's hydrometers are hydrometers of constant immersion and variable weight. They differ from the above. For instance, Nicholson's hydrometer consists of a hollow metal float, always submerged, below which is suspended a dish loaded with weights. Above the float is supported a shallow dish on a thin vertical wire. On this wire is a mark which is brought to the surface of the liquid by the weights in the upper and lower dishes. These weights determine the specific gravity of the liquid in which the hydrometer is immersed.

Refinements.—In laboratory work where great refinement is necessary the exact determination of specific gravities involves quite intricate formulas and extremely careful observations. The formulas include reduction of weighings to *vacuo*, and various temperature reductions.

Gases.—When we speak of the specific gravity of a gas we must have clearly in mind its *pressure* and *temperature*, and to what *standard* it is referred. The specific gravity of a unit mass of gas varies directly as its density and inversely as its volume. For constant temperature the density varies directly as the pressure, for constant pressure the density varies inversely as the temperature, meaning of course the temperature above absolute zero.*

The "standard" pressure of the gas determined is taken at, or reduced to, one "standard" atmosphere. Now a standard atmospheric pressure is about 14.7 lbs. per square inch, near enough for all practical engineering work. But it is not a fixed quantity. In *French units* it is assumed as a pressure equivalent to a column of mercury at 0° C. (32° F.), 760 mm (= 0.76 meter = 29.921 ins.) in height, and acted upon by an intensity of gravity, *g*, equal to that of Paris. This value of *g* has been determined as equal to an acceleration of 980.94 *c m* (= 9.8094 meters = 32.183 ft.) per sec. Now the specific gravity of mercury at 0° C. is taken at 13.596 (Regnault's determination, 13.5959; commonly assumed at 13.6); hence the pressure of a standard atmosphere at Paris = $76 \times 13.596 = 1033.3$ grams per sq. centimeter = 10.333 kilograms per sq. meter (= 14.697 lbs. per sq. in. = 2116.37 lbs. per sq. ft.). It is thus seen that the atmospheric pressure may be stated in terms of a column of mercury, or as a pressure per unit of area; and that these values are dependent on the temperature (mainly affecting the density of the mercury, and very slightly the air), the specific gravity of the mercury (affected by temperature and value of *g*), the value of *g* (affected by latitude, and elevation above sea level), the latitude, and the distance above sea level. In view of this, English units are often used, with round units of 16° C., 30 ins. of mercury, and 14.7 lbs. per sq. ft. Thus:

In *English units* the "standard" pressure is often assumed equivalent to a column of mercury at 60° to 62° F. (16° C.), 30 inches (762 millimeters) in height, and acted upon by an intensity of gravity *g* equal to that at 45° latitude. This gives a pressure practically the same as that derived from the French standard, namely, 14.7 lbs. per sq. in.

The standard temperature of the gas whose specific gravity is determined should be taken at or reduced to 0° C. (32° F.) for French units, or 60° to 62° F. (16° C.) for English units. The temperature reduction should be stated in all cases.

The standard substance referred to in determining the specific gravities of gases is air at 0° C. (32° F.), with the barometer at 760 mm (29.921 ins.) or one standard atmospheric pressure. Sometimes air at 60° or 62° F. is used. The specific gravity of the air multiplied by the sp grav of the gas referred to it = the sp grav of the gas with reference to water. Water at its maximum density, 4° C., is the standard, but sometimes 60° or 62° F. is used.

One cubic foot of air at	0° C. (32° F.)	weighs	0.0807 lb.
" " " " "	4° C. (39.1° F.)	"	0.0796 "

Brandy.....	.924	57.62			

* Based on weight of water at 62.36 lbs. per cubic foot, i.e., at 16° C. (= 60.8° F.)

SOLIDS AND MISCELLANEOUS.
6.—WEIGHTS AND SPECIFIC GRAVITIES OF WOODS.*
 (From Circular No. 15, U. S. Dep't of Agric.—Div. of Forestry.)
 (See also Table 7.)

No.	Name of species.	Num- ber of trees.	Num- ber of me- chanical tests.	Average		Localities and number of trees from each.
				specific gravity of dry wood.	weight per cu. ft. † Lbs.	
1	Longleaf Pine.....	68	6,478	0.61	38.0	Alabama, coast plain (22) a; uplands (6); hill district (6); Georgia, undulating uplands (6); South Carolina, coast plain (7); Mississippi, low coast plain (2) Louisiana, low coast plain, gravelly soil (7); sandy loam (6); Texas, low coast plain (6).
2	Cuban Pine.....	12	2,113	.63	39.3	Alabama, coast plain (6); Georgia, uplands (1); South Carolina, coast (5).
3	Shortleaf Pine.....	22	1,831	.51	31.8	Alabama, uplands (4); Missouri, low hilly uplands (6); Arkansas, low hilly uplands (6); Texas, uplands (6).
4	Loblolly Pine.....	32	3,335	.53	33.1	Alabama, mountainous plateau (8); low coast plain (6); Arkansas, level flood plain (5); Georgia, level coast plain (6); South Carolina, low coast plain (7).
5	White Pine.....	17	540	.38	23.7	Wisconsin, clay uplands (5); sandy soils (4); sandy loam (5); Michigan, level drift lands (3).
6	Red Pine.....	8	412	.50	31.2	Wisconsin, drift (5); Michigan (3).
7	Spruce Pine.....	4	696	.44	27.4	Alabama, low coast plain.
8	Bald Cypress.....	20	3,396	.46	28.7	South Carolina, pine barren (6); river bottom (4); Louisiana, coast plain, border of lake (4); Mississippi, Yazoo bottom (3); upland (3).
9	White Cedar.....	4	384	.37	23.1	Mississippi, low plain.
10	Douglas Spruce.....	...	225	.51	31.8	(From lumber yard.)
11	White Oak.....	12	1,009	.80	49.9	Alabama, ridges of Tennessee Valley (5); Mississippi, low plain (7).
12	Overcup Oak.....	10	911	.74	46.1	Mississippi, low plain (7); Arkansas, Mississippi bottoms (3).
13	Post Oak.....	8	256	.80	49.9	Alabama, Tennessee Valley (5); Arkansas, Mississippi bottom (3).
14	Cow Oak.....	11	935	.74	46.1	Alabama, Tennessee Valley (4); Arkansas, Mississippi bottoms (3); Mississippi, low plain (4).
15	Red Oak.....	7	299	.73	45.5	Alabama, Tennessee Valley (5); Arkansas, Mississippi bottom (2). b
16	Texas Oak.....	3	479	.73	45.5	Arkansas, Mississippi bottom.
17	Yellow Oak.....	5	222	.72	44.9	Alabama, Tennessee Valley (5).
18	Water Oak.....	4	132	.73	45.5	Mississippi, low plain (4).

* Nos. correspond with similar numbers in Tables 1 to 6, Sec. 28, Strength and Resistance of Materials.

† This column supplied by author, assuming specific gravity at 62° F.; thus, weight = spec grav $\times$ 62.36.

a Sixteen of these were bled trees to study the effects of boxing.

b These two should probably be classed as Southern Red Oak. They were collected before the distinction was finally decided upon.

Note.—The values for specific gravity here given refer to "dry" wood of test material, i. e., wood containing variable amounts of moisture below 15 per cent; the moisture effect has therefore not been taken into account, but more careful experiments indicate that its influence on specific gravity at such low per cent is so small that it may be neglected for practical purposes.

7.—AVERAGE WEIGHTS AND SPECIFIC GRAVITIES OF WOODS.

GENERAL TABLE.

Walnut, Black.....	.58	36.2	3.02			
Willow.....	.49	30.6	2.55			

Note that treated timbers will weigh from 5 to 20 lbs. per cu. ft. more than the untreated timbers, well seasoned. Beech, well treated, will receive 18.5 lbs. per cu. ft. of zinc chloride solution or about $\frac{1}{3}$ that quantity of creosote oil; pine, about the same quantities, usually a little less; and oaks about $\frac{1}{4}$ the above quantities. In general, the harder woods increase in weight less than the softer; exact quantities depend upon the specifications.

.9	56.1816	4.6818	.0325 125	56.124	4.6770	.0324 800
1.0	62.4240	5.2020	.0361 250	62.360	5.1967	.0360 889

Example.—What are the weights per cu. ft., per ft. B. M., and per cu. in., of a wood whose specific gravity is 0.61, water at 16° C.?

Solution.—	Cu. Ft.	Ft. B. M.	Cu. In.
.60	37.416	3.118	.02165
.01	.624	.052	.00036
.61	38.040 lbs.	3.170 lbs.	.02201 lb.

Note that for the same specific gravity compared with water at 4° C. the resultant weight is 1 part in 1000 greater than when compared with water at 16° C.; that is, a volume of water at the lower temperature is $\frac{1}{1000}$ of 1% heavier than an equal volume at the higher temperature. As the specific gravity of many substances varies greatly, depending upon the particular specimens selected for test, it will be noted that water at either temperature may generally be used as a basis for calculating the weight of the material. This is especially allowable for woods, building stones and other natural materials subject to variable composition, texture, and degrees of moisture. With liquids the variation of the substance is less marked; and with gases the temperature of the water with which it is compared should always be stated, as well as the temperature and pressure of the gas.

28.—STRENGTH AND RESISTANCE OF MATERIALS.

I. GENERAL PRINCIPLES.

The theory of the resistance of beams is explained in Sec. 15, Mechanics, page 298. The following discussion is pertinent to the subjoined tables, and to general working formulas.

a. Stresses and Resistance.

Stress f = force acting on any plane section of a material, produced either directly or by transmission; as, for instance, by leverage. It is measured usually in lbs. per sq. in. (or lbs. per sq. ft.), that is, in units of force per unit of area. The three primary stresses are *tension*, *compression* and *shear*. Transverse *bending* is accompanied by all three of the primary stresses. *Torsion* or twisting is usually treated as shear.

Strain e = percentage of distortion produced by stress. All strains can be reduced primarily to tension, compression of shearing, although torsion (mainly shear) is sometimes classed separately.

Modulus of elasticity $E = \frac{\text{Stress } f}{\text{Strain } e}$ (within the "elastic limit") = a constant. This is equivalent to stating that "Stress is proportional to strain" (Hooke's law), the stress f being equal to the applied load per square inch of cross-section, and the strain e , the percentage of resulting deformation of the material in the direction in which the force acts. If the material is in tension there obtains $E_t = \frac{f_t}{e}$, in which f_t equals tensile stress per sq. in.; if in compression, $E_c = \frac{f_c}{e}$; if in shear, $E = \frac{f_s}{e}$; if in torsion, $E_{tw} = \frac{f_{tw}}{e}$. Within practical limits, the moduli of elasticity for tension and compression are regarded by most engineers as equal for the same class of material.* If this is true the neutral axis in the beam under flexure (and also in the ideal column under concentric loading) will pass through the center of gravity of the section and remain stationary for all safe loadings. This is fundamental to the present theories of beams and columns.

Modulus of elasticity E is assumed to mean the tension or compression modulus unless otherwise stated or characterized, and will be so considered hereafter. If a weight is suspended at the lower end of a rod one inch in cross-section, producing an equal stress f in the rod, then will $f = \frac{E}{1000}$ when the rod is extended $\frac{1}{1000}$ part of its length,† i. e., when $e = 0.001$; $f = \frac{E}{500}$ when the extension is $\frac{1}{500}$ or $e = 0.002$; etc. In general, $f = Ee$. It is easy to see, then, that if these ideal conditions of elasticity could continue to the point where $e = \text{unity}$, f would equal E . Hence, the modulus or "coefficient" of elasticity is sometimes defined as that force which will stretch a rod of unit cross-section to double its length, based, of course, on the original length of rod and on the cross-section remaining constant. Long before this 100 per cent deformation can obtain, however, we reach the "elastic limit" or limit of elasticity of the material.

* The modulus of elasticity for most materials varies more or less with the intensity of stress, and is different for tension and compression of the same material, the difference becoming more apparent as the stresses increase. Hence, the neutral axis of beams varies in position with the amount of loading.

† The original length is used by the engineer for simplicity, although the final, or some distorted, length might be more applicable.

Elastic limit, and yield point.—Within the elastic limit of the material the strain is proportional to the stress or load, and when the latter is removed the material will return to its original length, form or position. (In other words, a perfectly elastic material or a material strained within the elastic limit is capable of transmitting all the energy that it receives, none of it being absorbed in internal work.) If, however, the material has been strained (by stress) in excess of or "beyond" the elastic limit it will begin to "yield" and the resulting deformation will increase *more rapidly* than the increase of stress or load. Hence the term "yield point" used to denote a point just beyond the elastic limit of the material. In Fig. 1, which illustrates the method of plotting the relation between stress and strain for any material, y is the yield point; $o-e.l.$ is a straight line showing "stress proportional to strain" within the elastic limit; and u is the position of ultimate strength, showing the relation between stress and strain at the "breaking point." The yield point is often almost coincident with the elastic limit.

Fig. 1.

The elastic limit is affected more or less by static-, repeated-, and alternating stresses.

Ultimate strength—ultimate stress.—The ultimate strength of material is the ultimate stress per sq. in. which the material is capable of resisting, up to the point of breaking. This is shown in Fig. 1 as point u . In testing material the stress is increased gradually by incremental loading, and the breaking point is always above the yield point.

The ultimate strength of material may be affected by the kind of stress or stresses to which it is subjected.

Static stress, or stress in one direction, tends to raise the elastic limit.

Repeated stresses, or stresses varying in intensity in one direction (either in tension or in compression, etc., and never reversing or passing through zero), tend to raise the elastic limit, sometimes materially, even when the stresses are well below it; and at the same time they tend to lower the ultimate strength. The latter will be the more marked the greater the number of repetitions and the wider their range.

Alternating stresses, or stresses passing through zero from tension to compression or vice versa, or from positive to negative shear, torsion, etc., in a vibratory manner, as often occurs in actual structures, tend to act injuriously in lowering both the elastic limit and the ultimate strength. Hence, working alternating stresses should be kept low.

Working stress and factor of safety.—The working stress is the maximum (safe) stress allowed by the designing engineer in his calculations, and from the previous discussion it will be seen that its value may vary greatly. In selecting the proper working stresses we must consider: (1) the kind of material, its physical qualities, and its durability; (2) the kind of loading, and the nature of the stresses; (3) the probable life of the structure, whether permanent or temporary. In general, the working stresses must be well within the elastic limit of the material, for any possible loading, and during any age of the completed* structure. The ratio of the ultimate strength to the working strength is called the factor of safety; thus,

$$\text{Factor of safety} = \frac{\text{ultimate strength}}{\text{working stress}}$$

The reason for basing the safety factor on the ultimate strength instead of on the elastic limit is that the former is more definitely ascertained; but the elastic limit is also considered to a certain extent, perhaps indirectly, in fixing the working stress.

With reference to the same kinds of loading or stresses, we select larger factors of safety for natural materials, as wood and stone, than we do for

* Concrete and reinforced concrete structures are not considered "completed" until the cement has set to that degree of hardness consistent with the working stresses adopted and based on the "age" of the concrete. Concrete structures grow stronger with age; wooden structures, weaker.

manufactured materials, as steel and iron. The obvious reason for this is that the ultimate strength of the manufactured material may be expected to vary but little from the specification, say 8 to 10 per cent, whereas the ultimate strength of wood and stone, even of the same quality, may vary 100% or more; furthermore, tests of metals at the same heat will determine the general character of the material for heat, while the physical properties of natural materials are not so determined, excepting for the particular piece under test. Again, fibrous substances, as stone, are more uncertain than fibrous substances, weaknesses are less easily detected; and hence stone should have more factors of safety than wood.

Factors of safety may be considered to range from 3, for static loads on steel, under favorable conditions, up to 20 or 30, for impact loads on masonry, due to moving machinery.

Resilience = work.—If a weight W is applied *gradually* to a rod of sectional area A , and length l , equal to volume $Al = V$, the elongation will be equal to $\frac{W}{A} \times \frac{l}{E}$; and as W is applied gradually, the work done in stretching the rod $= \frac{W}{2} \times s = \frac{W^2 l}{2AE}$. If f represents the stress per unit area, then $\frac{W}{A} = f$, and the work $= \frac{f^2}{2E} \times Al$; but $Al =$ the volume V , hence the resilience or work $= \frac{f^2 V}{2E}$. This is called the *elastic resilience* when the stress is within the elastic limit of the material.

Similarly, if a *beam* is loaded in the middle with a concentrated weight W applied gradually, the deflection at the center will equal $\frac{W l^3}{48EI}$; the average load $= \frac{W}{2}$, the total work performed $= \frac{W}{2} \times \frac{W l^3}{48EI}$. But from the theory of beams, the bending moment $M_s = \frac{W}{2} \times \frac{l}{2}$, equals $M_s = \frac{f l^2}{2}$; and, substituting this value of W in the above, we have

$$\text{Resilience or work} = \frac{W^2 l^3}{96EI} = \frac{f^2 l^3}{6Ey^3} = \frac{f^2 A l^3}{6Ey^3} = \frac{f^2}{2E} \cdot \frac{r^2}{3y^3} \cdot Al;$$

$$\text{or, in terms of volume it is equal to } \frac{f^2 r^2}{6Ey^3} \cdot V = \frac{f^2}{2E} \cdot \frac{r^2}{3y^3} \cdot V.$$

By the last equation it can be compared directly with the resilience of a rod. The above equations will represent the *elastic resilience* of a beam for concentrated loading at the middle, when f (the outer fiber stress) is equal to the elastic limit of the material. In general, the resilience of the beam is obtained by multiplying the greatest allowable applied load, by one-half the deflection.

The *resilience* of a material may be defined as the capacity of the material to absorb and give out energy, measured in units of inch-pounds.

For different kinds of stress we have the following values for the work of deformation of any material. By proper substitution for the particular kind and shape of the material the resilience can be obtained in definite units; and the result will be the *elastic resilience* value of f represents the elastic limit of the material:

Stress.		Resilience
Tension, direct,	- - - - -	$\frac{f^2 V}{2E}$
Compression, direct,	- - - - -	$\frac{f^2 V}{2E}$

* See Table 1, Sec. 31, Properties and Tables of Beams and Girders.
 † The *modulus of resilience* is the resilience of a unit volume (cubic inch) of the material. It is obtained by making $V =$ unity, in the above equations.

Stress.	Resilience.
Bending, in beam, from concentrated load,	$\frac{f^2 r^2}{6E y^2} V$
" " " " uniform load,	$\frac{4f^2 r^2}{15E y^2} V$
" " rectangular beam ($b \times h$), <i>concentr.</i> load,	$\frac{f^2}{18E} V$
" " " " " " uniform "	$\frac{4f^2}{45E} V$
" " " beam with <i>unif.</i> longitudinal bending moment, $\frac{f^2}{6E} V$	
Torsion, in solid rod,	$\frac{5f^2}{8E_{\text{tor}}} V$

where V = volume of material under action, in cubic inches;

E = modulus of elasticity of the material,

r = radius of gyration, in inches;

y = distance from neutral axis to extreme outer fiber, in inches;

f = extreme outer fiber stress, in lbs. per sq. in.

b. Loading and Impact.

Sudden Loading.—In the discussion of resilience, the loading is considered as applied gradually, the resultant being a static load; and at no time is the distortion greater than that due to the load statically applied. The intensity of stress increases constantly from zero to a maximum, and consequently the average stress equals one-half the maximum stress. If, however, a load just "touching" a rod or beam, so as to produce the least amount of stress, is applied *suddenly* but without impact, that is, "let go," the distortion will practically be *doubled*, and hence the fiber stress, deflection, and work performed will be *double* that produced by resilience as when the load is applied gradually. For this reason "live loads" on structures, and especially train loads on bridges, are considered as "sudden loads," the working stresses for which are usually but *one-half* the working stresses for dead or static loads.

Impact is the energy of the blow when one mass, possessing momentum, comes in contact with another mass. At the instant of contact each gives energy to and absorbs energy from the other, and if they were perfectly elastic (an ideal condition never realized in practice) none of the energy would be dissipated into heat.

The mathematical analyses of many operations, as pile driving, water ram in pipes, etc., are dependent upon reducing the *energy* of the blow to an equivalent static *force*; but no formula yet devised correctly represents the relation. To do so, it must take into consideration the element of distortion or *distance* (energy is a measure of force $\times$ distance), the inertia of the resisting mass, the loss of energy in heat, in deformation of material, etc. Partial analyses of some of these conditions have been attempted, upon certain assumptions, but they are of doubtful utility unless accompanied by data from practical experiments. The term "impact" is sometimes wrongly applied to "sudden loading."

For discussion of pure impact, see Sec. 15, Mechanics, pages 303, 304.

II. TABLES OF STRENGTH OF MATERIALS.

32	Sweet Gum.....	118	1,400	800

* To an indentation of 3 per cent of the height of the specimen.

† Actual tests on "dry" material not reduced for moisture.

The above tests made under the direction of J. B. Johnson, for the Division of Forestry, are given in full because, aside from the actual values of the results, they show clearly the wide variation which may be expected in submitting timber to actual test.

Relation Between Weight and Strength of Timber.—For want of space the author omits two diagrams which exhibit close relations of *weight* and *breaking strength* of timber, but the relations may be shown analytically as follows:

Compression, endwise; pounds per square inch:

For pines and hickories = weight (dry) in pounds per cu. ft. $\times$ 195.

For oaks = weight (dry) in pounds per cu. ft. $\times$ 170.

Bending, transverse; pounds per square inch (fiber stress):

For pines and hickories = weight (dry) in pounds per cu. ft. $\times$ 300.

For oaks = weight (dry) in pounds per cu. ft. $\times$ 255.

It is to be noted that the *dry* weights per cubic foot are to be used. (See Foot-note to Table 6, Sec. 27, *Weights and Specific Gravities*, pages 470, 471.)

7.—TIMBER IN TENSION, COMPRESSION, BEARING, BENDING AND SHEAR.

Practical Working Units for Columns, Beams, etc.*

(See Author's Column Formula, Sec. 82, Columns, page 500.)

[Note.—Values in table are in thousand pounds per square inch; hence, multiply by 1000 to reduce to pounds per square inch. Thus 12.0 = 12000.]

Timber	Safety Factor.	Tena.	Compression.			Bearing.		Bending.		Shear

*See Recommendations and Remarks on following page.

RECOMMENDATIONS AND REMARKS ON PRECEDING TABLE:

Tension.—Use safety factor of 8 for tension, in bridges and buildings.

Compression.—Use safety factor of 5 for compression, in bridges and buildings, under ordinary circumstances.

Bearing.—Use safety factor of 5 for end bearing, with grain; and safety factor of 4 for side bearing, across grain.

Bending.—Use safety factor of 6 for extreme fiber of railroad stringers and for joists; use factor of 5 for floorbeams and for large girders.

Shear.—Use safety factor of 5 for shearing, with grain. Note that the longitudinal shearing force H per unit of length of beam is equal to the total vertical shear V multiplied by the statistical moment Q of an area above plane of shear, about neutral axis, and divided by the moment of inertia I of total section. Thus, $H = \frac{VQ}{I}$. (See Sec. 31, Beams and

Girders, page 565.)

* Mainly on the authority of Alfred E. Hunt, and the Pittsburg Reduction Co., principal manufacturers of aluminum in the United States. Assuming the conductivity of copper wire at .97 and aluminum wire at .62, the area of aluminum wire must be 1.565 times that of copper to carry the same electrical current; and on this basis the aluminum wire, for any given length, say per mile, will weigh .47 as much as copper wire. Hence, when the price of aluminum wire per pound is .47 that of copper, or when copper is 2.13 that of aluminum, they will be on about an equal footing for economy on transmission lines. The relative cross-sections of wire of different conductivities, for equal electric transmission, are about as follows: Copper .97 conductivity equals area 1.00; aluminum at .60 conductivity = area 1.617, at .61 cond = area 1.59, at .62 cond = area 1.565, at .63 cond = area 1.54. The physical properties of pure aluminum are increased by cold rolling and forging. There are two principal alloys with copper, viz., aluminum-bronze and copper-hardened aluminum, the latter containing from 2 to 15 per cent copper.

* The physical properties of gun-metal vary greatly with the method of casting, and also with the position of the metal in the cast. The tenacity increases with the specific gravity and pressure; it is greater at the bottom of the melt than at the top.

† The relative conductivity of silicon-bronze wire to pure copper at 1.00 varies from .95 for the soft wire down to .35 for the hard.

‡ Composed of about 60 parts copper, 38 to 40 parts zinc, 2 to 4 iron, 1 to 2 tin.

a See Proposed Standard Specifications for Gray Iron Castings, p. 498.

° The Am. Soc. for Testing Materials adopted (by letter-ballot on Nov. 15, 1904—Vol. IV, page 96) the following tests for tensile and transverse strength of malleable castings: *Tensile Test*. The tensile strength of a standard test bar (a bar 1 in. square and 14 ins. long, without chills and with ends perfectly free in the mold) for castings under specification shall not be less than 40000 lbs. per sq. in.; and the elongation measured in 2 ins. shall be not less than 2½ per cent. *Transverse Test*. The transverse strength of a standard test bar, on supports 12 ins. apart, pressure being applied at center, shall be not less than 3000 lbs., deflection being at least ¼ inch.

¶ Wrought iron is now seldom manufactured except for blacksmith iron and water pipes. Steel which often goes under the double name of "Iron and Steel," in specifications, has entirely superseded iron for structural work because it is stronger and more cheaply manufactured.

Gray Iron Castings.—Proposed Standard Specifications, adopted by letter-ballot of the Am. Soc. for Testing Materials, September 1, 1900. Digest:—1. Unless furnace iron is specified, all gray castings are to be made by the cupola process. 2. The sulphur contents to be as follows: Light castings, not $>.08\%$; medium castings, not $>.10\%$; heavy castings, not $>.12\%$. 3. "Light" castings are those having any section less than $\frac{1}{2}$ in. thick; "heavy" castings are those in which no section is less than 2 in. thick; "medium" castings are those not included under light or heavy. 4. *Transverse Test.* The minimum breaking strength of the "Arbitration Bar" (a round bar $1\frac{1}{2}$ ins. dia. and 15 ins. long) under transverse load shall not be under: Light castings, 2500 lbs.; medium castings, 2900 lbs.; heavy castings, 3300 lbs. In no case shall the deflection be under .10 in. (The loads to be applied at middle of bars resting on supports 12 ins. apart. The deflection at rupture. Two sets of 2 bars each from each heat; one set from the first, and the other set from the last iron going into the casting. Where the heat exceeds 20 tons, an additional set of two bars shall be cast for each 20 tons or fraction thereof above this amount. In case of change of mixture during the heat, one set of two bars shall also be cast for every mixture other than the regular one. Each set of 2 bars is to go into a single mold. The bars shall not be rumpled or otherwise treated, being simply bushed off before testing.) *Tensile Test.* Where specified, this shall not run less than: Light castings, 18000 lbs. per sq. in.; medium castings, 21000 lbs. per sq. in.; heavy castings, 24000 lbs. per sq. in. The tensile test shall be made on the "Tensile Test Piece*" ($3\frac{1}{2}$ ins. long with sectional diameter 1 in. round). 5. The quality of the iron going into castings under specification shall be determined by means of the "Arbitration Bar." The tensile test is not recommended, but in case it is called for, the "Tensile Test Piece" turned up from any of the pieces of the transverse test shall be used. The expense of the tensile test shall fall on the purchaser.

Fig. 2.—Mold for "Arbitration Bar" showing a cross-section and a side view. The cross-section shows a central core of 10" Pipe Core, surrounded by a 10" Pipe Core, and a 10" Pipe Core. The side view shows the mold with a 10" Pipe Core, a 10" Pipe Core, and a 10" Pipe Core. The mold is 15" high and 10" wide. The core is 10" high and 10" wide. The mold is 15" high and 10" wide. The core is 10" high and 10" wide.

* See Fig. 3, page 501.

* High ult tens str of steel was employed in the following structures: St. Louis Br., 100000; Plattsmouth Br. and Niagara Centilever, 80 000; Bismarck Br., 80-90000 comp., 70-80000 tens; Susquehanna Br. (B. & O.), Ky. and Ind. Centilever, and Van Buren Br., 80000 comp, 70000 tens. The Manufacturers' Standard (1903) employs three grades: Rivet (48-58000), Railway Bridge (55-65000), Medium (60-70000); elastic limit not less than $\frac{1}{2}$ ult str; percentage of elongation, 1400000+ ultimate strength.

† The Bethlehem Steel Co. guarantees the following physical properties in solid and hollow steel forgings of different sizes; the tensile test specimen to be used being the U. S. Standard as adopted by the Am. Soc. for Testing Materials (see Fig. 5, page 501).

Class of Steel Forging.		Tensile Strength. Lbs. per Sq. In.	Elastic Limit. Lbs. per Sq. In.	Elongation. Per Cent.	Contraction of Area. Per Cent.	Dimensions of solid and hollow forgings in which the physical qualities mentioned to the left are guaranteed.
Nickel Steel Oil-Tempered.	(1)	95 000	65 000	21	50	Solid or Hollow forgings, no diameter or thickness of section to exceed 3 ins.
	(2)	90 000	60 000	22	50	Solid forgings of rectangular sections not exceeding 6 ins. thick; or Hollow forgings, the walls of which do not exceed 6 ins. in thickness.
	(3)	85 000	55 000	24	45	Solid forgings of rectangular sections not exceeding 10 ins. thick, or Hollow forgings, the walls of which do not exceed 10 ins. in thickness.
Nickel Steel Annealed.	(1)	80 000	50 000	25	45	Solid or Hollow forgings, no diameter or thickness of section to exceed 10 ins.
	(2)	80 000	45 000	25	45	Solid forgings, no diameter to exceed 20 ins., or thickness of section 15 ins.
	(3)	80 000	45 000	24	40	Solid forgings over 20 ins. diam.

Class of Steel Forging.		Tensile Strength Lbs. per Sq. In.	Elastic Limit. Lbs. per Sq. In.	Elonga- tion. Per Cent.	Contraction of Area. Per Cent.	Dimensions of solid and hollow forgings in which the physical qualities mentioned to the left are guaranteed.
Carbon Steel Oil- Tempered.	(1)	90 000	55 000	20	45	Solid or Hollow forgings, no diameter or thickness of section to exceed 3 in.
	(2)	85 000	50 000	22	45	Solid forgings of rectangular sections not exceeding 6 ins. in thickness. Hollow forgings, the width of which do not exceed 6 ins. in thickness.
	(3)	80 000	45 000	23	40	Solid forgings or rectangular section not exceeding 10 ins. in thickness. Hollow forgings, the width of which do not exceed 10 ins. in thickness.
Carbon Steel Annealed.	(1)	80 000	40 000	22	35	Solid or Hollow forgings, no diam. or thickness of section to exceed 10 in.
	(2)	75 000	37 500	23	35	Solid forgings, no diameter to exceed 20 ins., thickness of section 15 in.
	(3)	70 000	35 000	24	30	Solid forgings over 20 ins. diam.

Digest of Standard Specifications for Steel, adopted by the Am. Soc. for Testing Materials. (See Proceedings, Vols. I, V, etc.)

	Ref.	Adopted
i. Stand. Spec. for Structural Steel for Bridges.	Vol. V.	Sept. 1, 1900
ii. Stand. Spec. for Open-hearth Boiler Plate and Rivet Steel.	- - - - -	Vol. I.
iii. Standard Specifications for Steel Rails.	-	Vol. VI. Proposed.
iv. Standard Specifications for Steel Castings.	-	Vol. V. Sept. 1, 1900
v. Standard Specifications for Steel Axles.	-	Vol. V. Sept. 1, 1900
vi. Standard Specifications for Steel Forgings.	-	Vol. V. Sept. 1, 1900

i. STRUCTURAL STEEL FOR BRIDGES.

1. Steel shall be made by the open-hearth process. 2. The chemical and physical properties shall conform to the following limits:

Elements Considered.	Structural Steel.	Rivet Steel.	Steel Casting
Phosphorus Max. { Basic Acid	0.04 per cent. 0.08 "	0.04 per cent. 0.04 "	0.05 per cent. 0.08 "
Sulphur Max.	0.05 "	0.04 "	0.05 "
Ult. tensile strength Lbs. per sq. in.	Desired 60 000	Desired 50 000	Not less than 65 000
Elong.: Min. per cent in 8 ins. (Fig. 3)	1 500 000* Ult. tens. str.	1 500 000 Ult. tens. str.	
Elong.: Min. per cent in 2 ins. (Fig. 4)	22		18
Character of fracture	Silky	Silky	{ Silky or fine granular
Cold bend without fracture	180 degrees flat †	180 degrees flat ‡	
			90° on dia. = t × the thickness (d = 3t)

* See par. 11. † See par. 12, 13 and 14. ‡ See par. 15.

The yield point, as indicated by the drop of beam, shall be recorded in the test reports. 3. If the *ult str* varies more than 4000 lbs. from that desired, a *re-test* may be made, at the discretion of the inspector, on the same gauge, which, to be acceptable, shall be within 5000 lbs. of the desired ultimate.

4. *Chemical determinations* for percentages of carbon, phosphorus, sulphur and manganese to be made from test ingot at time of pouring; check analyses from finished material may show 25 per cent above required limits. 5. Specimens for tensile and bending tests for *plates, shapes and bars* shall be made by cutting coupons from the finished product, which shall have both faces rolled and both edges milled to the form shown by Fig. 4; or with both edges parallel; or they may be turned to a dia of $\frac{1}{4}$ in. for a length of at least 9 ins., with enlarged ends. 6. *Rivet rods* shall be tested as rolled. 7. For *pins and rollers*, specimens shall be cut from the finished rolled or forged bars in such a manner that the center of the specimen shall be 1 inch from surface of bar. Specimen for tensile test shall be turned to the form shown by Fig. 5; specimens for bending test shall be $1 \times \frac{1}{4}$ in. in section. 8. *Steel Castings*.

The number of tests will depend on the character and importance of the castings. Specimens shall be cut cold from coupons molded and cast on some portion of one or more castings from each melt or from the sink-heads, if the heads are of sufficient size. The coupon or sink-head, so used, shall be annealed with the casting before it is cut off. Test specimens to be of the form prescribed for pins and rollers. 9. *Material* which is to be used without annealing or further treatment shall be tested in the condition in which it comes from the rolls. When material is to be annealed or otherwise treated before use, the specimens for tensile test, representing such material, shall be cut from properly annealed or similarly treated short lengths of the full section of the bar. 10. *Number of tests*. At least one tensile and one bending test shall be made from each melt of steel as rolled. In case steel differing $\frac{1}{8}$ inch and more in thickness is rolled from one melt, a test shall be made from the thickest and thinnest material rolled. 11. *Elongation*. For material less than $\frac{1}{4}$ inch and more than $\frac{1}{8}$ inch in thickness the following modifications will be allowed in the requirements for elongation:

- (a) For each $\frac{1}{8}$ in. in thickness below $\frac{1}{4}$ in., a deduction of $2\frac{1}{2}$ from the specified percentage.
- (b) For each $\frac{1}{8}$ in. in thickness above $\frac{1}{4}$ in., a deduction of 1 from the specified percentage.

12. *Bending tests* may be made by pressure or by blows. Plates, shapes and bars less than 1 in. thick shall bend as called for in par. 2. 13. *Full-sized material* for eye-bars and other steel 1 inch thick and over, tested as rolled, shall bend cold 180° around a pin whose diam is twice the thickness of the bar, without fracture on outside of bend. 14. *Angles* $\frac{1}{4}$ inch and less in thickness shall open flat, and angles $\frac{1}{2}$ inch and less in thickness shall bend shut, cold, under blows of a hammer, without sign of fracture. This test to be made only when required by inspector. 15. *Rivet steel*, when nipped and bent around a bar of the same diam as the rivet rod, shall give a gradual break and a fine, silky, uniform fracture.

ii. OPEN-HEARTH BOILER PLATE AND RIVET STEEL.

1. *Steel* shall be made by the open-hearth process. 2. *Chemical properties* of the three classes shall conform to the following limits:

	Plate or boiler steel.	Fire-box steel.	Extra soft steel.
Phosphorus shall not exceed	Acid 0.06 per cent. Basic 0.04 "	0.04 per cent. 0.03 "	0.04 per cent. 0.04 "
Sulphur shall not exceed	0.05 "	0.04 "	0.04 "
Manganese	0.30 to 0.60	0.30 to 0.50	0.30 to 0.50

Fig. 3.

Fig. 4.

Fig. 5.

3. *Steel for boiler rivets* shall be of the extra soft class as specified in p and 4. 4. *Physical properties* of the three classes shall be as follows:

	Flange or boiler steel.	Fire-box steel.	Extra soft steel.
Tensile strength, lbs. per sq. in.	55000 to 65000	52000 to 62000	45000 to 55000
Yield point, in lbs. per sq. in. shall not be less than	$\frac{1}{2}$ tens str	$\frac{1}{2}$ tens str	$\frac{1}{2}$ tens str
Elongation, per cent in 8 ins., shall not be less than	25 (see par. 5)	26 (see par. 5)	28 (see par. 5)

5. *Elongation.* For material less than $\frac{1}{4}$ inch and more than $\frac{1}{8}$ inch thickness the following modifications will be allowed in the requirements for elongation:

- For each $\frac{1}{4}$ in. in thickness above $\frac{1}{8}$ in., a deduction of 1 from specified percentage.
- For each $\frac{1}{8}$ in. in thickness below $\frac{1}{4}$ in., a deduction of $2\frac{1}{2}$ from specified percentage.

6. *Bending tests.* The three classes shall conform to the following bending tests; the bending-test specimen to be $1\frac{1}{2}$ ins. wide if possible, and for material $\frac{1}{4}$ in. in thickness or less, it shall be of the same thickness as that of the material from which it is cut; but it may be $\frac{1}{2}$ in. thick for material over $\frac{1}{4}$ in. thick. (Round rods shall be tested of full size as rolled.): (c) The specimens cut from the rolled material as specified above, shall be subjected to a cold bending test, and also to a quenched bending test. The cold bending test shall be made on the material in the condition in which it is received; and prior to the quenched bending test, the specimen shall be heated to a light cherry-red as seen in the dark and quenched in water, the temperature of which is between 80 and 90° F. (d) Flange or boiler steel, fire-box steel and rivet steel (all three classes), both before and after quenching, shall bend cold 180° flat on itself without fracture on outside of bend. 7. *Homogeneity.* For fire-box steel a sample taken from a broken tensile test specimen shall not show any single seam or cavity more than $\frac{1}{4}$ in. long in either of the three fractures obtained on the test for homogeneity as described below in paragraph 12. 8. *Test pieces and testing.* The standard specimen of 8 in. gauged length, shall be used to determine the physical properties specified in par. 4 and 5. The standard shape of the test specimen for sheared plates shall be as shown in Fig. 4, preceding, the piece to be of same thickness as the plate. For other material the test specimen may be the same as for sheared plates, or it may be planed or turned parallel throughout its entire length, and in all cases where possible two opposite sides of the test specimens shall be the rolled surfaces. Rivet rounds and small rolled bars shall be tested of full size as rolled. 9. *One tensile specimen* will be furnished from each plate as it is rolled, and two tensile test specimens will be furnished from each melt of rivet rounds. In case any one of these develops flaws or breaks outside of the middle third of the gauged length, it may be discarded and another test specimen substituted therefor. 10. For material $\frac{1}{4}$ in. or less in thickness the bending test specimens shall have the natural rolled surface on two opposite sides. The bending test specimens cut from plates shall be $1\frac{1}{2}$ ins. wide, and for material more than $\frac{1}{4}$ in. thick they may be $\frac{1}{2}$ in. thick; the sheared edges may be planed or planed. The bending test specimens for rivet rounds shall be of full size as rolled. The bending test may be made by pressure or by blows. 11. One cold and one quenched bending specimen will be furnished from each plate as it is rolled. Two cold and two quenched bending specimens will be furnished from each melt of rivet rounds. The homogeneity test for fire-box steel shall be made on one of the broken tensile test specimens. 12. The homogeneity test for fire-box steel is made as follows: A portion of a broken tensile test specimen is either nicked with a chisel or grooved on a machine, transversely about $\frac{1}{8}$ in. deep, in three places about 2 in. apart. The first groove should be made on one side, 2 ins. from the square end of the specimen; the second, 2 ins. from it on the opposite side; the third, 2 ins. from the last, and on the opposite side from it. The specimen is then put in a vice, with the first groove about $\frac{1}{4}$ in. above the jaws, care being taken to hold it firmly. The projecting end of the specimen is then broken off by means of a hammer, a number of light blows being used, and the bending being away from the groove. The specimen

broken at the other two grooves in the same way. The object of this treatment is to open and render visible any seams due to failure to weld up, or to foreign interposed matter, or cavities due to gas bubbles in the ingot. After rupture, one side of each fracture is examined, a pocket lens being used if necessary, and the lengths of seams and cavities determined.

iii. STEEL RAILS.

1. *Manufacture.* (a) The entire process of manufacture and testing shall be in accordance with the best current practice, and conform carefully to the following instructions: (b) Ingots shall be kept in a vertical position in the pit heating furnaces until ready to be rolled, or until the metal in the interior has time to solidify. (c) No bled ingots shall be used. (d) Sufficient material shall be discarded from the top of ingot to insure sound rails. 2. *Chemical composition.* Rails of the various weights per yard specified below shall conform to the following limits in chemical composition:

	50 to 59 pounds. Per cent.	60 to 69 pounds. Per cent.	70 to 79 pounds. Per cent.	80 to 89 pounds. Per cent.	90 to 100 pounds. Per cent.
Carbon.....	.35-.45	.38-.48	.40-.50	.43-.53	.45-.55
Phosphorus, shall not ex- ceed	.10	.10	.10	.10	.10
Silicon, shall not exceed....	.20	.20	.20	.20	.20
Manganese.....	.70-1.00	.70-1.00	.75-1.05	.80-1.10	.80-1.10

3. One *drop test* shall be made on a piece of rail not less than 4 ft. and not more than 6 ft. long, selected from every fifth blow of steel. The test shall be taken from the top of the ingot. The rail shall be placed head upwards on the supports, and the various sections shall be subjected to the following impact tests under a free falling weight:

Weight of Rail—lbs. per yard, 45	to 55;	height of drop, 15 ft.
" " " 55+	to 65	" 16 "
" " " 65+	to 75	" 17 "
" " " 75+	to 85	" 18 "
" " " 85+	to 100	" 19 "

If any rail break when subject to the drop test, two additional tests taken from the top of the ingot will be made of other rails from the same blow of steel, and if either of these latter tests fail, all the rails of the blow which they represent will be rejected, but if both of these additional test pieces meet the requirements, all the rails of the blow which they represent will be accepted. 4. *Finishing temperature.* The number of passes and speed of train shall be so regulated that on leaving the rolls at the final pass the temperature of the rail will not exceed that which requires a shrinkage allowance at the hot-saws, for a 30-ft. rail of 100-lb. section, of $6\frac{1}{4}$ ins., and $\frac{1}{8}$ in. less for each 5-lb. decrease of section. These allowances to be decreased at the rate of $\frac{1}{16}$ in. for each second of time elapsed between the rail leaving the finishing rolls and being sawn. No artificial means of cooling the rails shall be used between the finishing pass and the hot-saws. 5. The *drop testing machine* shall have a tup of 2000 lbs. weight, the striking face of which shall have a radius of not more than 5 ins., and the test rail shall be placed head upwards on solid supports 3 ft. apart. The anvil block shall weigh at least 20000 lbs., and the supports shall be part of, or firmly secured to, the anvil. The report of the drop test shall state the atmospheric temperature at the time the test was made. (The Am. Soc. C. E. standard rail section is recommended. See Sec. 30, page 560, and Sec. 56, page 1060.)

iv. STEEL CASTINGS.

1. Steel for castings may be made by the open-hearth, crucible or Bessemer process. Castings to be annealed unless otherwise specified. 2. *Ordinary castings*, those in which no physical requirements are specified, shall not contain over 0.40 per cent of carbon, nor over 0.08 per cent of phosphorus. 3. Castings which are *subjected to physical test* shall not contain over 0.05 per cent of phosphorus, nor over 0.05 per cent of sulphur.

4. Tested castings shall be of three classes: "Hard," "Medium," and "Soft." The *minimum physical qualities* required in each class shall be as follows:

	Hard Castings.	Medium C.	Soft C.
Tensile strength, lbs. per sq. in.	85 000	70 000	60 000
Yield point, lbs. per sq. in. [.45 T.]	38 250	31 500	27 000
Elongation, per cent in two ins.	15	18	22
Contraction of area, per cent	20	25	30

5. *Drop test.* A test to destruction may be substituted for the tensile test in the case of small or unimportant castings, by selecting three castings from a lot. This test shall show the material to be ductile and free from injurious defects, and suitable for the purposes intended. A lot shall consist of all castings from the same melt or blow, annealed in the same furnace charge. 6. *Percussive test.* Large castings are to be suspended and hammered all over. No cracks, flaws, defects, nor weakness shall appear after such treatment. 7. *Bending test.* A specimen $1\frac{1}{2}$ in. shall bend cold around a diam. of 1 in. without fracture on outside of bent portion, through an angle of 120° for "soft" castings, and 90° for "medium" castings. 8. *Tensile test piece.* The standard turned test specimen (Fig. 5, p. 501), $\frac{1}{2}$ in. diam. and 2-in. gauged length, shall be used to determine the physical properties specified in par. 4. 9. The number of standard test specimens shall depend upon the character and importance of the castings. A test piece shall be cut cold from a coupon to be molded and cast on some portion of one or more castings from each melt or blow or from the sink heads (in case heads of sufficient size are used). The coupon or sink-head must receive the same treatment as the casting or castings, before the specimen is cut out, and before the coupon or sink-head is removed from the casting. 10. *Test piece for bending.* One specimen for bending test, $1" \times \frac{1}{4}"$, shall be cut cold from the coupon or sink-head of the casting or castings as specified in par. The bending test may be made by pressure or by blows.

V. STEEL AXLES.

1. *Manufacture.* Steel for axles shall be made by the open-hearth process. 2. *Chemical properties.* There will be three classes of steel axles which shall conform to the following limits in chemical composition:

	Car and Tender Truck Axles. Per cent.	Driving and Engine Truck Axles.	
		(Carbon Steel) Per cent.	(Nickel Steel) Per cent.
Phosphorus shall not exceed	0.06	0.06	0.04
Sulphur " " "	0.06	0.06	0.04
Manganese " " "		0.06	
Nickel			3. to 4.

3. *Physical properties.* For car and tender truck axles no tensile test shall be required. 4. The minimum physical qualities required in the two classes of driving and engine truck axles shall be as follows:

	Driving and Engine Truck Axles	
	(Carbon Steel)	(Nickel Steel)
Tensile strength, pounds per sq. in.	80 000	80 000
Yield point, pounds per sq. in.	40 000	50 000
Elongation, per cent in 2 ins.	20	25
Concentration of area, per cent.	25	45

5. *Drop test.* One axle selected from each melt, when tested by the drop test described in par. 9, shall stand the number of blows at the height specified in the following table without rupture and without exceeding, as the result of the first blow, the deflection given. Any melt failing to meet these requirements will be rejected:

Diam. of axle at center, inches...	4½	4¾	4⅞	4⅞	4¾	5½	5½
Number of blows.....	5	5	5	5	5	5	7
Height of drop, feet.....	24	26	28½	31	34	43	43
Deflection (max., 1st blow), inches.	8½	8½	8½	8	8	7	5½

6. Carbon steel and nickel steel driving and engine truck axles shall not be subject to the above drop test. 7. *Test pieces and testing.* The standard turned test specimen (Fig. 5, page 501), ½ in. diam. and 2-in. gauged length, shall be used to determine the physical properties specified in par. 4. 8. For driving and engine truck axles one longitudinal test specimen shall be cut from one axle of each melt. The center of this test specimen shall be half-way between the center and outside of the axle. 9. The points of supports on which the axle rests during tests must be 3 ft. c. to c.; the tup must weigh 1640 lbs.; the anvil, which is supported on springs, must weigh 17500 lbs.; it must be free to move in a vertical direction; the springs upon which it rests must be 12 in number, of the kind described on drawing; and the radius of supports and of the striking face on the tup in the direction of the axis of the axle must be 5 ins. When an axle is tested it must be so placed in the machine that the tup will strike it midway between the ends, and it must be turned over after the first and third blows, and when required, after the fifth blow. To measure the deflection after the first blow prepare a straight edge as long as the axle, by reinforcing it on one side, equally at each end, so that when it is laid on the axle, the reinforced parts will rest on the collars or ends of the axle, and the balance of the straight edge not touch the axle at any place. Next place the axle in position for test, lay the straight edge on it, and measure the distance from the straight edge to the axle at the middle point of the latter. Then after the first blow, place the straight edge on the now bent axle in the same manner as before, and measure the distance from it to that side of the axle next to the straight edge at the point farthest away from the latter. The difference between the two measurements is the deflection. The report of the drop test shall state the atmospheric temperature at the time the tests were made.

vi. STEEL FORGINGS.

1. Steel forgings may be made by the open-hearth, crucible or Bessemer process. 2. *Chemical properties.* There will be four classes of steel forgings which shall conform to the following limits in chemical composition:

	Forgings of Soft or Low Carbon Steel.	Forgings of Carbon Steel not Annealed.	Forgings of Carbon Steel, Oil Tempered or Annealed.	Locomotive Forgings	Forgings of Nickel Steel, Oil Tempered or Annealed.
	Per cent.	Per cent.	Per cent.	Per cent.	Per cent.
Phosphorus shall not exceed	0.10	0.06	0.04	0.05	0.04
Sulphur " " "	0.10	0.06	0.04	0.05	0.04
Manganese " " "				0.60	
Nickel.....					3. to 4.

3. *Physical properties.* The minimum physical qualities required of different sized forgings of each class shall be as follows:

	Tensile Strength.	Yield Point.	Elongation in 2 ins.	Contraction
	Lbs. per sq. in.		Per cent	
<i>Soft Steel or Low Carbon Steel.</i>				
For solid or hollow forgings, no diam. or thickness of section to exceed 10".....	58 000	29 000	28	
<i>Carbon Steel Not Annealed.</i>				
For solid or hollow forgings, no diam. or thickness of section to exceed 10".....	75 000	37 500	18	
		Elastic Limit.		
<i>Carbon Steel Annealed.</i>				
For solid or hollow forgings, no diam. or thickness of section to exceed 10".....	80 000	40 000	22	
For solid forgings, no diam. to exceed 20" or thickness of section 15".....	75 000	37 500	23	
For solid forgings, over 20" diam.....	70 000	35 000	24	
<i>Carbon Steel, Oil Tempered.</i>				
For solid or hollow forgings, no diam. or thickness of section to exceed 3".....	90 000	55 000	20	
For solid forgings of rect. sections not exceeding 6" in thickness; or hollow forgings the walls of which do not exceed 6" in thickness.....	85 000	50 000	22	
For solid forgings of rect. sections not exceeding 10" in thickness; or hollow forgings, the walls of which do not exceed 10" in thickness.....	80 000	45 000	23	
<i>Locomotive Forgings.....</i>	80 000	40 000	20	
<i>Nickel Steel Annealed.</i>				
For solid or hollow forgings, no diam. or thickness of section to exceed 10".....	80 000	50 000	25	
For solid forgings, no diam. to exceed 20" or thickness of section 15".....	80 000	45 000	25	
For solid forgings, over 20" diam.....	80 000	45 000	24	
<i>Nickel Steel, Oil Tempered.</i>				
For solid or hollow forgings, no diam. or thickness of section to exceed 3".....	95 000	65 000	21	
For solid forgings of rect. sections not exceeding 6" in thickness; or hollow forgings, the walls of which do not exceed 6" in thickness.....	90 000	60 000	22	
For solid forgings of rect. sections not exceeding 10" in thickness; or hollow forgings, the walls of which do not exceed 10" in thickness.....	85 000	55 000	24	

4. *Bending test.* A specimen $1 \times \frac{1}{2}$ in. shall bend cold 180° around the following diameters without fracture on outside of bent portion: $\frac{1}{2}$ " diam. forgings of soft steel, and for forgings of nickel steel annealed; 1" diam. forgings of carbon steel annealed, if under 20" diam. and for forgings of carbon steel oil-tempered, and for forgings of nickel steel oil-tempered; $1\frac{1}{2}$ " diam. for forgings of carbon steel not annealed, and for forgings of carbon steel annealed, if 20" in diam. or over. For locomotive forgings no bending test will be required. 5. The standard turned test specimen (Fig. 5, p. 501), $\frac{1}{2}$ in. diam. and 2-in. gauged length, shall be used to determine physical properties specified in par. 3. 6. The number and location of test specimens to be taken from a melt, blow, or a forging shall depend upon character and importance and must therefore be regulated by individual cases. The test specimens shall be cut cold from the forging or full-size prolongation of same parallel to the axis of the forging and half-way between the center and outside, the specimens to be longitudinal, i. e., the length of the specimen to correspond with the direction in which the metal is drawn out or worked. When forgings have large ends or collars, the test

specimens shall be taken from a prolongation of the same diameter or section as that of the forging back of the large end or collar. In the case of hollow shafting, either forged or bored, the specimen shall be taken within the finished section prolonged, half-way between the inner and outer surface of the wall of the forging. 7. The specimen for bending test, $1 \times \frac{1}{2}$ in., shall be cut as specified in par. 6. The bending test may be made by pressure or by blows.

C. Building Stones, Cements, Etc.

9.—COMPRESSION, TENSION, BENDING, ETC., OF ABOVE MATERIALS. [Pounds per square inch.]

Material.	Compression. (Ult.)	Tension. (Ult.)	Bending. (Extr. Fiber.)
*Bluestone (New York).....Use	12 000	1200	2500
Brick, soft, inferior.....	1 000	60

Pressed 4000 to 11000.....	6 000		
Vitrified, tests on 2" cubes.....	38 000	Extra high record.	

*High Records for Compressive Strength of Bluestone (Hudson R.).—41422 lbs. per sq. in.; 38000 lbs. per sq. in., at capacity of machine without failing. Test made on 2-in. cube.

† Tests at Watertown Arsenal (1883): Bay State, medium burned, 10390 to 12709; Face, hard burned, 11050 to 16734; Common, hard burned, 12995 to 22351 lbs. per sq. in. The direction of pressure was at right angle to the largest face. (For tests of Brick Piers, see page 522.)

‡ A commission appointed by the Nat'l Brick Man'frs' Ass'n (1895) to study the best methods for testing paving brick concluded that the "Rattler" test was the most valuable; that the absorption and cross-bearing tests were of little use; and the crushing test was useless. A standard rattler test was formulated as follows: The rattler barrel is 28" diam. $\times$ 20" long; it is a 14-sided polygon, supported on trunnions, the shaft not being continuous through the barrel; it is built of cast iron heads and either cast or wrought iron staves 6" wide; the space between the staves, for the escape of dust, not to exceed $\frac{1}{8}$ " in width; rate of rotation 30 revs. per min., with 28 and 32 as limits; each test requiring 1800 revs., or 60 mins. at standard speed; number of brick per test charge, 9 to 12; an official test to be the average loss in per cent of initial charge from two separate charges; the brick to be absolutely dry when tested; each charge to contain, in addition to the brick, 225 lbs. of $1\frac{1}{2}$ in. cast iron cubes at 0.88 lb. each when new, and also 75 lbs. cast iron shot $2\frac{1}{2} \times 2\frac{1}{2} \times 4\frac{1}{2}$ ins. at about 7 lbs. each (to be renewed when the loss in weight is 10%). The losses in the brick vary from 12 to 25%. Mr. Edward Orton, Jr., (see Proc. Am. Soc. for Test'g Mat'ls, Vol. V, page 296) considers 17% loss for heavy traffic streets and 20% loss for light residence streets to constitute reasonable limits for standard tests.

* Compression tests made on cylindrical specimens one inch in height and with a diam. ($1\frac{1}{2}$ in.) that will give an area of one sq. in. Note the dropping off in tensile strength of neat Portland, from 3 to 6 mos. also the same characteristic when used with Ottawa sand. Long time tests extending up to a year or more, frequently show a dropping off in tensile strength in a few weeks or months, and later increased strength. This doubtless due to some changed condition in the process of hardening. At age of two years the tensile strength of neat Portland may be assumed 14 to 18% greater than 6 mos.; and the tensile strength of neat Natural 18 to 22% greater. Portland mortars increase about 18%, and Natural mortars about 6%, in the period between 6 mos. and two years.

Concrete, Portland. Compression.*Varying Mixtures, Columns, 60 days.*

The following formula for strength of short, round, plain (unreinforced) stone concrete columns, is deduced from tests reported by Prof. A. N. Talbot (see *Eng. News*, Sept. 26, 1907). The columns were generally 12 ins. in diam and 10 ft. long. The concrete was a wet mixture of proportions 1 : $1\frac{1}{2}$: 3, 1 : 2 : 4, 1 : 3 : 6, and 1 : 4 : 8. The forms were removed in 10 days and the columns were tested in 60 days. The straight-line formula is:

$$\text{Ultimate compressive strength, lbs. per sq. in.} = \frac{12000}{S_s + S_t} - 400 \dots \dots \dots$$

in which S_s = ratio of sand to cement, } Thus, in 1 : 2 : 4 concrete
and S_t = ratio of stone to cement. } $S_s = 2$, and $S_t = 4$.

The following values are deduced from equation (1):

Mixture.....	1:1:2	1:1½:3	1:2:4	1:2½:5	1:3:6	1:3½:7	1:4:8
Ult. comp. str.,	(3600)	2267	1600	1200	933	743	600
lbs. per sq. in..							

The value 3600, for 1:1:2 concrete, is beyond the range of the tests but it is believed to be fairly reliable.

6" Stone Concrete Cubes, 1:2:4 mix, 30 days.

Compression tests on 6-inch cubes, by Prof. Edgar Marburg (Proc. Am. Soc. Test'g Mat'ls, 1904), give mean average values as follows: Wet, or rather medium, mixtures (amount of water 16% of combined weight of cement and sand, the water flushing freely to top during tamping), av. 1650 lbs. per sq. in., with 1364 min. and 2503 max.; two cubes mixed "dry" with 10% water, instead of 16%, developed a compressive strength, without crushing, of 2778 lbs. per sq. in., the limit of the testing machine being 100000 lbs.

8" and 12" Trap-rock Concrete Cubes, 1:2.3:4.6 mix.

(Watertown Arsenal Tests.)

These were wet, or rather medium, mixtures (amount of water 15.2% of combined weight of cement and sand):

2- 8" cubes developed	(2630 and 2440), av. 2535, lbs. per sq. in. at 30 days
2- 8" "	(3830 and 3300), av. 3565, lbs. " " 60 "
2-12" cubes	(3360 and 3100), av. 3230, lbs. " " 30 "
2-12" "	(3940 and 4780), av. 4360, lbs. " " 60 "
1-12" cube	5170 lbs. " " 6 mos

Age, months.....	1,	2,	6,	1,	2,	6,	1,	2,	6,
Ratio of strength, 8" cubes..	1.0	1.40	...	0.71	1.0	...	...	...	...
12" " ..	1.0	1.35	1.6	0.74	1.0	1.19	0.62	0.84	1.0

Note that the size of the cube seems to be a function of the crushing strength of concrete, as it is with natural stone—granite, limestone, etc.

The elastic limit of concrete under compression is about $\frac{1}{3}$ to $\frac{1}{2}$ (say $\frac{1}{3}$) the ultimate strength.

Concrete, Portland. Tension.

(Tests by Prof. W. K. Hatt, 1901-2.)

No.	Kind Stone.	Age in Days.	Modulus of Elasticity, lbs. per sq. in.	Elongation Strength at Rupture 1 part in.	Strength lbs. per sq. in.	Where Broken.
1	1:2:4	35	2 700 000	11 660	300	At pin.
2	1:2:4	33	2 400 000	8 750	305	"
3	1:2:4	28	1 400 000	4 400	360	"
4	1:2:4	26	1 900 000	7 700	280	"
Average.....			2 100 000	7 000	311	...
5	1:2:4	28		910	281	Body

The tension specimens were 4" square in cross-section, with gauged length of 24", and 30" between centers of pins, through heads 8" diam. The concrete was fairly dry concrete intended to be plastic after a thorough ramming. About 5.5% of water by weight was added to the mortar. Prof. Hatt says: These tension tests were not satisfactory for determination, since the heads of the bars, with some exceptions, pulled off; but it is believed that the strength of the body of the bars did not differ greatly from the loads recorded at the point of rupture of the heads. They served, however, very well for the determination of modulus of elasticity.

The elastic limit of concrete under tension is very near the ult. str.

Concrete, Portland. Compression, Tension, Bending, and Shearing.*

That some broad relations exist between the compressive strength, tensile strength, modulus of rupture (extreme fiber stress due to bending) and shearing strength of concrete, is quite probable; but it is certain that no constant ratios can be assigned. Even for the same proportions of mixture the above mentioned ratios would vary with the consistency of the mix and the age of the concrete. We have seen also that compressive strength per sq. in. increases with the size of the cube or mass,

*For Shearing values of stone and concrete, see Proc. A. S. T. M., Vol. VIII., 1906.—By H. H. Quimby.

but we have every reason to believe that a like increment would for tension, bending and shearing, although the compressive stress cubes is influenced greatly by the shearing resistance of the

The following ratios are approximate only:

Compressive Strength.	Tensile Strength.	Mod. of Rupture.	Shearing Strength.
1.00	0.08 to 0.12		
....	1.00	1.4 to 1.8	1.2 to

Concrete, Portland. Modulus of Elasticity (E) of concrete increases with richness of the mixture and with the age; it decreases (usually) as stress increases; and is greater (usually) when the concrete is under compression than when under tension, although for practical purposes of design the latter distinction is seldom recognized. Some authorities assume the ratio of the modulus of elasticity of concrete to that of steel as 1:9 or 230 000 (kilograms per sq. meter), making in English units = 3 270 000 (lbs. per sq. in.), this value being used in calculations of reinforced concrete beams. In American practice a high value of E would be assigned to a rich mixture of concrete after 3 to 6 months. (See Sec. 25, Masonry, page 445.)

Concrete, Portland. Heat Effect. The coefficient of linear expansion of concrete may be assumed, for all practical purposes, to equal that of steel, namely, .0000063 per degree Fahrenheit, or a change in length of .01 ft. per 100 ft. in length for each 15 degrees variation in temperature. To this fact, the use of reinforced-concrete is made possible.

Heating tests on concrete prisms, by Prof. Ira H. Woolson, University, 1905-6, indicate a marked decrease in strength and modulus of elasticity after the specimens had been subjected to a temperature of 750° F., and a decided decrease in both of these physical characteristics after exposure to 1500° F. It is to be noted that broken concrete stood the heating effect far better than the smooth-surfaced gravel concrete, which latter practically disintegrated at the same temperature, maintained for 2 to 3 hours. The specimens were 4" to 7" in size which naturally exposed, in the furnace, a proportionately large "surface" to "mass," and hence no direct conclusions can be drawn from these tests as to the fire-resisting qualities of concrete in actual construction. The tests, however, showed the inferiority of gravel concrete under the conditions imposed.

Concrete, Natural. The compression, tension, modulus of rupture and shearing of natural (Rosendale) cement concrete may be assumed to be about 50% of the values for Portland cement concrete, unless other similar brands of known value are used.

Concrete, Cinder.

 Plaster of Paris. Tension, 70; compression, 700.

III. HEAT EFFECT ON VARIOUS SUBSTANCES.

General Discussion.—Substances are usually classed from standpoint as gases, liquids and solids, according to their condition in the natural atmospheres (with regard to both temperature and pressure).

A Gas may be defined as a substance which when enclosed in a vessel will assume the shape and volume of the vessel; a Liquid is a substance which when enclosed in a vessel will assume the shape of that portion of the vessel which corresponds to the volume of the liquid itself; while a Solid will assume neither the shape nor the volume of an arbitrary vessel.

All gases may be reduced to liquids by lowering the temperature sufficiently, and subjecting it to the required pressure.

The *Critical Point* or *Critical Temperature* of a gas may be defined as that temperature above which it cannot be liquefied, no matter how much pressure exerted upon it. If the temperature of a gas is above its critical temperature it is known as *vapor*, and pressure alone will not reduce it to a liquid. Every gas has its critical temperature, and at this point a sudden change from gas to liquid is accompanied by a change of volume—with a clear line of demarcation when only the gas is so transformed.

It depends upon the temperature and pressure, and may be defined as the temperature above which the body of the liquid passes

of *Vaporization* is the quantity of heat absorbed in boiling, the liquid to a gaseous condition merely, without increase of temperature; and, conversely, it is the quantity of heat given out in condensing of vapor to that of a liquid merely, without decrease of temperature. The latent heat of vapor may be expressed (1) in British Thermal Units, one B. T. U. being equivalent to 778 ft.-lbs. of work; (2) in calories, one calorie being equal to 4.18 meter-kilograms of work, or the quantity of heat required to raise the temperature of one pound of water near its temperature of maximum density (39.1° F.), or 1 meter-kilogram of work, or the quantity of heat required to raise the temperature of one kilogram of water 1° C. at or near its temperature of maximum density; (3) in foot-pounds, one foot-pound being equal to the quantity of heat required to raise the temperature of one pound of the substance which can be raised, by the application of the heat, 1° C. from 0° C.; (4), equivalent to (3), the temperature of the substance which can be raised, by the application of the latent heat to one pound of the substance. (See also, Section 69, Steam and Gas Power.)

Fusion is analogous to latent heat of vaporization, and the quantity of heat absorbed in liquefaction, i. e., transition to a liquid condition merely, without increase in temperature, since the laws of solidification are similar to those of the process.

tion. If a gas under pressure is allowed to expand suddenly if under sufficiently high pressure and allowed to expand will fall to such an extent that it will liquefy. The ice by cylinder and piston, produces cold by the expansion

g-mixtures. Certain substances when properly mixed in
ons and to the required fineness will produce a decided
ature. The lowest temperature ever attained by mixture
a sulphuric ether and solid carbon dioxide, known as
re." The most common mixture is that of salt and ice,
ature of -22°C . may be attained.

Zero of Temperature is that temperature at which heat On the centigrade scale it is about -273.7°C , usually $^{\circ}\text{C}$. All the known gases except helium have been liquefied. It is found that this gas does not liquefy at the low temperature. The absolute temperature scale is based on the absolute zero.

Note.—Some substances, as glass and iron, have no definite melting point, passing gradually from the solid to the liquid state, by what is known as *vitreous fusion*.

THERMODYNAMICS—REFERENCES.

In Sec. 69, Steam and Gas Power, the following subjects are defined and discussed, and may be considered somewhat pertinent to the present matter in this Section:

British Thermal Unit (B.T.U.)

Density.

Entropy.

Entropy Diagrams.

External and Internal Work.

First Law of Thermodynamics.

Heat.

Heat Equivalent of External Work.

Heat Equivalent of Internal Work.

Heat of Combustion.

Heat of the Liquid.

Heat of Vaporization.

Heating Power of Fuels.

Mechanical Equivalent of Heat.

Mechanical Equivalents of Heat
(Table).

Pressure of Saturated Steam.

Specific Heat of the Liquid.

Specific Volume.

Specific Volume of Saturated Steam.

Specific Volume of Water.

Steam.

Steam Tables.

Thermal Energy.

Total Heat.

Thermal Units.

Thermal Unit Equivalents (Table).

Coefficient of Expansion.—The coefficient of expansion of a body is the rate of increase per deg. of temperature, usually based on the Fahrenheit scale.

Let us take a cube of metal, and denote the length of each edge by L when the temperature is t° . At the higher temperature of T° the length of each edge expands to $L+x$. Then we have—

$$\begin{array}{lll} \text{Length of each edge} = & \text{At } T^\circ. & \text{At } t^\circ. \\ & L+x; & =L. \\ \text{Surface of each face} = & (L+x)^2; & =L^2. \\ \text{Volume of the cube} = & (L+x)^3; & =L^3. \end{array} \quad \begin{array}{l} \text{Expansion for } T^\circ-t^\circ. \\ \\ 2Lx+x^2 \\ 3L^2x+3Lx^2+x^3. \end{array}$$

Hence (for one degree), we have—

$$\begin{array}{ll} \text{Coef. of Linear Expansion} & = \frac{1}{T^\circ-t^\circ} \times \frac{x}{L} \quad (\text{Exact.}) \\ \text{Coef. of Surface Expansion} & = \frac{1}{T^\circ-t^\circ} \times \frac{2Lx+x^2}{L^2} \quad (\text{Approx.}) \\ \text{Coef. of Volumetric Expansion} & = \frac{1}{T^\circ-t^\circ} \times \frac{3L^2x+3Lx^2+x^3}{L^3} = \frac{1}{T^\circ-t^\circ} \left(\frac{3x}{L} \right). \end{array}$$

The approximate results are obtained from the assumption that, as itself is so extremely small, any power of x greater than unity (as x^2 and x^3) would be practically zero.

It is thus seen that the Surface expansion and the Volumetric expansion are, respectively, *two* and *three* times the Linear expansion.

* Values in table are for Linear expansion. For Surface expansion multiply by 2 and 3, respectively. To change from Cent. to Fahr., mult by $\frac{9}{5}$; from Fahr. to Cent., mult by $\frac{5}{9}$ = 1.8. Note that a range of temperature of 180° F = 100° C.

IV. FRICTIONAL RESISTANCE OF MATERIALS.

In 1831-4 General Arthur Morin, of the French Artillery, conducted a series of experiments on friction, which were published in his "*Lecons de Mecanique Pratique*." The results of these experiments have been reprinted extensively in various works because of the care with which the tests were conducted. Tables 15, 16 and 17 are reproduced here from Joseph Bennett's translation of the above work.* Table 16, from Rankine's *Applied Mechanics*, is also added in order to show that author's version of Morin's tests. Later experiments, notably those of Beauchamp Tower,† have added to our knowledge of the laws of friction.

The three fundamental laws of friction deduced by Morin, who experimented with pressure up to about 30 lbs. per sq. in., are as follows:

1st. Friction is directly proportional to the pressure; the coefficient of friction [natural tang. of the angle of repose] being constant at all pressures.

2nd. The total friction and the coefficient of friction are independent of the areas in contact; the total pressure remaining the same. [This naturally follows from the 1st law.]

3rd. The coefficient of friction is independent of the velocity of one surface on the other.

It is perhaps well to suggest here that Table 15 be not used with undue reliability, as any jarring of the structure, the conditions of the atmosphere, etc., might affect the tabular results. Table 16 would be safer to use where stability is desired.

Mr. Tower found in experimenting with revolving journals at high speeds and under heavy pressures, that the coefficient of friction, f , varied directly with the square root of the linear velocity, and inversely with the pressure. With good oil the value of f with revolving journals may be

$$\text{assumed at: } f = \frac{\sqrt{\text{Velocity in ft. per sec.}}}{4 \times \text{Pres. in lbs. per sq. in.}}$$

* "Fundamental Ideas of Mechanics," revised and translated by Joseph Bennett; D. Appleton & Co., New York, 1860. Published by permission.

* *Applied Mechanics*, published by Charles Griffin & Co., London.

Rolling Friction (Dry).—In the above discussion we have dealt with sliding friction only, which of course includes journal friction.—(See Tables 10 to 18).

Rolling friction is the resistance at the line of contact only, when a wheel or cylinder is rolled over a "smooth," (horizontal) surface, by a force acting parallel to the surface) applied at the axle of the wheel or roller of radius r inches, in moving the total load (W).

The general equation of rolling friction is,

$$F = \frac{CW}{r} \dots \dots \dots (1)$$

in which C , of equation (1), is a constant determined by experiment, for each kind of material rolling on each kind of material.

For iron or steel, rolling on iron or steel, $C = 0.02$, about.

Example.—A train weighing 1200 tons, with steel car-wheels 24 ins. in diameter, is drawn on a level track of steel rails, by an engine exerting a pulling force P . What part of P is required to overcome the rolling friction of the train?

Solution.—From equation (1), we have, by substitution,

Rolling friction $F = (0.02 \times 1200) \div 24 = 2$ tons. Ans.

Rolling friction is a factor in estimating the power required to swing trestles and drawbridges.

EXCERPTS AND REFERENCES.

Results of Tests of Materials Subjected to Combined Stresses (By E. Hancock. Proc. A. S. T. M., Vol. VIII., 1908).—Maximum stress as shear theories. Diagrams of tests.

Crushing Tests on Water-Soaked Timbers (By E. C. Sherman. Engr. News, July 1, 1909).—Diagrams of tests on water-soaked oak and yellow pine blocks, transverse to grain, proposed for supporting tracks for rolling caisson lock gates for Charles River dam. Result of tests showed transverse tests so low that cast iron chairs were substituted.

Crushing Tests of Brick and Terra-Cotta Piers (By A. N. Talbot and D. A. Abrams. Bulletin No. 27, Ill. Eng'g Exper. Sta.; Eng. News, Aug. 1909).—Summaries of the brick and terra-cotta tests are given below:

Concave-end blocks, 1 : 2 Port. (6 tests)...	2970	0.69	0.86	...

*All columns 12½ x 12½ ins. nominal, about 9½ ft. long; made from blocks of second shipment except where noted "Concave-end blocks;" all tests in two months.

†Estimated.

‡Blocks from second shipment, all of which were of good quality; enough blocks that appeared somewhat underburned or otherwise inferior were selected to make up one column.

The Effect of Fire on Building Materials (By Jas. E. Howard. Paper before the Natl. Assn. of Mutual Insurance Co's.; Eng. Rec., Dec. 3, 1910).—The following stresses in lbs. per sq. in. for various materials, when heated, correspond to a rise in temperature of 160° F.: Steel, 30000 lbs. per sq. in.; cast iron, 17000 to 13590 lbs. per sq. in.; granite, 6270 to 3200 lbs. per sq. in.; marble, 10800 to 2880 lbs.; slate, 13480 lbs.; sandstone, 3200 to 960 lbs.; hard burned brick, 4960 lbs.; light hard brick, 2230 lbs.; soft (salmon) brick, 248 lbs.; neat portland cement, 3710 lbs. per sq. in. Other experiments show that stones when even moderately heated do not return exactly to their primitive dimensions, but retain as a permanent set some of the expansion which they acquired when hot, although the permanent sets are comparatively small. Experiments on 12" x 12" sticks of Douglas fir, heated over a wood fire for 2½ hours, at about 1380° F., until they were from 7 ins., showed increased compressive strength in lbs. per sq. in. for the burned portion.

Gypsum as a Fireproofing Material (By H. G. Perring. Paper, Natl. Protection Assn.; Eng. Rec., Dec. 3, 1910).—Advantages in the use of plaster: (1) Low heat conductivity: the heat penetrates the plaster at a slow rate that in fires of ordinary duration the metal would hardly warm. (2) No appreciable expansion of plaster under heat action. Hence, no contraction and destructive cracking when water is applied to the fire. (4) Does not burn or support combustion. (5) Plaster is the best practical fireproofing material. (6) Plaster has the required strength for use in partitions and column coverings, and against fire streams. It is adaptable to any form of construction: even when used in slabs they can be readily cut or sawed to fit any desired location. (8) Plaster is low in cost. (9) Trim can be nailed to plaster fireproofing without the use of wood blocks or grounds. (10) Plaster blocks or boards, made of pure gypsum and wood fiber, are true and even and reduce the cost of plastering to a minimum.

Some Tests of Old Timber (By C. P. Buchanan. Eng. News, Dec. 8, 1910).—Crushing strength of 25-year-old and of new white pine, compared:

Area, sq. ins.	Crushing load, lbs. per sq. in.	Remarks.
SPECIMENS FROM BRIDGE.		
9.25	5780	Clear, bolt-hole mark ¼" deep on narrow side.
8.50	4795	Clear. Hart. Slightly decayed.
6.31	5950	Sound. One sap corner.
10.00	4920	Clear. Hart. Well defined season cracks.
9.25	5330	Large black knot in longer side and end.
10.00	5100	Clear.
6.00	5440	Clear and slightly decayed.
9.00	5060	Clear. Hart. Well defined season crack.
....	5300	Average of above 8 tests.
SPECIMENS FROM STOCK.

29.—PROPERTIES AND TABLES OF PLANAR SURFACES.

1.—GEOMETRICAL FIGURES.

Center of gravity indicated by heavy dot.
(Values are exact.)

NOTATION.

A = area of figure. $I = Ar^2$ = moment of inertia about axis $X-X$;
 $\sqrt{I+A}$ = radius of gyration about axis $X-X$. $S = \frac{I}{y}$ = section modulus
 $S_1 = \frac{I}{y_1}$; $S_2 = \frac{I}{y_2}$. a or y_0 = distance from axis considered to parallel axis through center of gravity.; x = length of strip of infinitesimal width distant y from neutral axis. All in inches.

Fig. 1.—Any figure; neutral axis $X-X$ through center of gravity.

$$A = \int_{-y_2}^{y_1} x dy \quad I = \int_{-y_2}^{y_1} xy^2 dy$$

$$r^2 = I + A \quad r = \sqrt{\frac{I}{A}}$$

$$S_1 = \frac{I}{y_1} \quad S_2 = \frac{I}{y_2}$$

Fig. 2.—Any figure; axis at base.

$$A = \int_0^{y_1} x dy \quad I = \int_0^{y_1} xy^2 dy$$

$$y_0 = \frac{\int_0^{y_1} y dA}{\int_0^{y_1} dA} = \frac{\int_0^{y_1} xy dy}{\int_0^{y_1} x dy}$$

$$r = \sqrt{\frac{I}{A}} \quad S = \frac{I}{y_1}$$

Fig. 3.—Any figure; axis $X'-X'$ parallel with neutral axis $X-X$.

$$I' \text{ (about } X'-X') = I + a^2 A$$

$$= \int_0^{y_1} xy^2 dy + a^2 A$$

(I is for neutral axis through cen of grav as in Fig. 1; a = p dist between the two axes.)

Fig. 4.—Triangle; axis through cen of grav.

$$A = \frac{bd}{2} \quad I = \frac{bd^3}{36}$$

$$y_1 = \frac{1}{3}d \quad y_2 = \frac{2}{3}d$$

$$I = \frac{\pi r_1^3 t}{3} = 1.5708 r_1^3 t$$

$$r = \frac{r_1}{\sqrt{2}} = 0.707 r_1$$

Fig. 51.—Semi-circular arc.*

$$y_1 = y_2$$

A, I and r same as for 50.

Fig. 52.—Semi-circular arc; axis through cen of grav.*

$$y_1 = r_1 \left(1 - \frac{2}{\pi}\right) = 0.3634 r_1$$

$$y_2 = \frac{2r_1}{\pi} = 0.6366 r_1$$

$$A = \pi r_1^2 = 3.1416 r_1^2$$

$$I = r_1^3 t \left(\frac{\pi}{2} - \frac{4}{\pi}\right) = 0.2976 r_1^3 t$$

$$r = r_1 \sqrt{\frac{1}{2} - \frac{4}{\pi^2}} = 0.308 r_1$$

(Note that I_{33} can be obtained from I_{30} by method explained under Fig. 3; using the minus sign, as $I_{32} < I_{30}$.)

Fig. 53.—Circular arc.*

$$y_1 = r_1 \left(1 - \frac{\sin \alpha}{\alpha}\right)$$

$$y_2 = r_1 \left(\frac{\sin \alpha}{\alpha} - \cos \alpha\right)$$

$$A = 2 r_1^2 \alpha t$$

$$I = r_1^3 t \left(\alpha + \sin \alpha \cos \alpha - \frac{2 \sin^3 \alpha}{\alpha}\right)$$

$$r = \sqrt{\frac{I}{A}}$$

(Note.—The angle α may be expressed in terms of π ; thus, $180^\circ = \pi$, $90^\circ = \frac{\pi}{2}$, etc.)

Fig. 54.—Circular arc.*

$$y_2 = 2 r_1 \frac{\sin^2 \frac{1}{2} \alpha}{\alpha} \quad y_1 = r_1 \sin \alpha - y_2$$

*Thickness of lines = t .

Fig. 54—Continued.

$$x_1 = r_1 \left(\frac{\sin \alpha}{\alpha} - \cos \alpha\right)$$

$$x_2 = r_1 (1 - \cos \alpha) - x_1$$

$$A = r_1^2 \alpha t$$

$$I = r_1^3 t \left(\frac{\alpha - \sin \alpha \cos \alpha}{2} - \frac{4}{3} x_1^2\right)$$

$$r = \sqrt{\frac{I}{A}}$$

Special Case.

For axis X' at base:

$$I = \frac{r_1^3 t}{2} (\alpha - \sin \alpha \cos \alpha)$$

$$r = r_1 \sqrt{\frac{1}{2} - \frac{\sin \alpha \cos \alpha}{2 \alpha}}$$

Fig. 55.—Corrugated sheet. ing corrugations to be curves, we have,*

b = Breadth of sheet before gating.

$$y_1 = \frac{d}{2}$$

$$A = b t$$

$$I = \frac{1}{30} d^3 b t = 0.1333 d^3 b t$$

$$r = d \sqrt{\frac{1}{30}} = 0.365 d$$

(Compare this with 49, 50, that semi-circular arcs would $r = 0.354 d$.)

Fig. 56.—Corrugated sheet.

$$y_1 = y_2 = \frac{d}{2}. \text{ Let}$$

F = area top flanges,

= area bottom flanges,

W = area of webs. Then

$$A = 2F + W$$

$$I = \frac{d^3}{2} \left(F + \frac{W}{6}\right)$$

$$r = \sqrt{\frac{I}{A}}$$

(Note.—The above value holds true for any inclination webs, from vertical to horizontal the upper and lower flanges equal areas).

4.—ROLLED SHAPES.

(See, also, Sections 30, 31, 32, following.)

In the following illustrations the center of gravity is indicated by a heavy dot.

Values are exact for shapes as outlined. These shapes do not show the actual rounded "fillets" because the latter are disregarded in structural calculations, except in special cases.

The flanges of I-beams and standard channels slope at the rate of 2 : 12 on their inner faces, equivalent to an angle of $9^{\circ} 28'$. The heavier sections of I-beams, channels and Z-bars are made by spreading the rolls, thereby increasing the width of flange; but most angles are rolled in "finishing" grooves, which maintain a standard width of flange for various thicknesses of metal.

Moment of inertia (I_{α}) about inclined axis.

—In the preceding illustrations (Figs. 1-70) we have confined our attention to moments of inertia about the coordinate axes $X-X$ and $Y-Y$, one of which is usually drawn parallel with a principal line of the figure, and the other at right angle to the first. It very often happens, however, that we wish to know the value I_{α} , the moment of inertia about an inclined axis making an angle α with the axis $X-X$, Fig. 71, about which latter axis I_x is the moment of inertia. This may be obtained from the following formula:

Fig. 71.

$$I_{\alpha} = I_x \cos^2 \alpha + I_y \sin^2 \alpha - 2K \cos \alpha \sin \alpha \dots \dots \dots (1)$$

In which $I_x = \iint y^2 dx dy$ = moment of inertia about axis $X-X$;

$I_y = \iint x^2 dx dy$ = moment of inertia about axis $Y-Y$;

I_{α} = moment of inertia about axis $\alpha-\alpha$;

α = angle between the axes $\alpha-\alpha$ and $X-X$, the functions of α to be considered algebraically; thus, $\sin \alpha$ is + in the 1st and 2nd quadrants, and - in the 3rd and 4th; while $\cos \alpha$ is + in the 1st and 4th, and negative in the 2nd and 3rd. Hence, $\cos^2 \alpha$ and $\sin^2 \alpha$ are always positive (+), while $\sin \alpha \cos \alpha$ becomes positive (+) when the axis $\alpha-\alpha$ lies in the 1st and 3rd quadrants, and negative (-) when it lies in the 2nd and 4th.

$K = \iint xy \, dx \, dy$ = double integration (summation) of dA ($= dx \, dy$, or $\square$) multiplied by its axial distances x and y (see Fig. 71). Those portions of the figure or surface considered which lie in the 1st and 3rd quadrants tend to make K positive (+), while those portions which lie in the 2nd and 4th quadrants tend to make K negative (-).

In solving equation (1) we find the values of I_x , I_y and K from the shape of the plane figure and with the coordinate axes $X-X$ and $Y-Y$ intersecting at the origin O . Then by assuming the proper value for the angle α we may solve equation (1) for I_{α} . Values of I_x and I_y for many figures are given under the preceding illustrations. We will now explain how K is derived.

Values of K in Equation (1).—The value of K is

$$K = \iint xy \, dx \, dy \dots \dots \dots (2)$$

bearing in mind what has previously been said regarding positive and negative values.

Secondly, the preceding formula (2) may also be expressed:

$$K = A x_0 y_0 \dots\dots\dots$$

In which A = area of the figure or plane surface,

$x_0 = +$ or $-$ distance from axis of $Y-Y$ to cen of grav

$y_0 = +$ or $-$ distance from axis of $X-X$ to cen of grav

all in inches. It is evident that when the cen of grav lies at the origin (Fig. 71) the value of K is zero; when in the 1st or 3rd quadrants, it is + and when in the 2nd and 4th, it is $-$. But the minus sign in equation must also be considered, as well as the algebraic value of $\cos \alpha$ since solving for $I \alpha$.

Thirdly, the figure may be cut up into smaller areas, each area b multiplied by its respective coordinate distances x and y to the cen of, of each area; thus,

$$K = \Sigma A_1 x_1 y_1 + A_2 x_2 y_2 + A_3 x_3 y_3 + \dots\dots\dots$$

The four following examples will illustrate the methods of finding value of K in Equation (1):—

$$(1) K = \int_0^d \int_0^b xy dx dy = \int_0^d \left[\frac{x^2}{2} y dy \right]_0^b = \frac{b^2}{2} \int_0^d y dy = \frac{b^2}{2} \left[\frac{y^2}{2} \right]_0^d = \frac{b^2 d^2}{4}.$$

$$\text{Or, } K = bd \cdot \frac{b}{2} \cdot \frac{d}{2} = \frac{b^2 d^2}{4} \text{ (second method).}$$

Fig. 71

$$(2) K = bd \left(b_1 + \frac{b}{2} \right) \left(-d_1 - \frac{d}{2} \right) \\ = -bd \left(\frac{bd}{4} + \frac{bd_1 + b_1 d + b_1 d_1}{2} \right).$$

$$\text{If } d_1 = 0, K = -bd \left(\frac{bd}{4} + \frac{b_1 d}{2} \right).$$

$$\text{If, also, } b_1 = 0, K = -\frac{b^2 d^2}{4}. \text{ (Compare with Fig. 72)}$$

Fig. 73

$$(3) K = \frac{b^2 d^2}{4} - \frac{b_1^2 d^2}{4} + \frac{b_1^2 d_1^2}{4} - \frac{b^2 d_1^2}{4}$$

$$\text{If } b_1 = b \text{ and } d_1 = d, K = 0.$$

But if $b = 0$ and $d_1 = 0$, there will remain for the 2nd

$$\text{quadrant, } K = -\frac{b_1^2 d^2}{4}.$$

Fig. 74

$$(4) K = K_1 + K_2 + K_3$$

$$= t(d-t)x_1 y_1 + bt \times 0 + t(d-t)(-x_3)(-y_3).$$

$$\text{But } x_1 = x_3 = \frac{b-t}{2}, \text{ and } y_1 = y_3 = \frac{d}{2}; \text{ hence}$$

$$K = \frac{1}{2} (bt - t^2) (d^2 - dt).$$

Fig. 75

Problem.—(1) Find the moment of inertia I_{α} , about the axis $\alpha_1 - \alpha_1$ of a square beam of cross-section $d \times d$, α_1 making an upward angle of 45° with the axis $X - X$; (2) find I_{α_2} about the axis $\alpha_2 - \alpha_2$ making a downward angle of 45° with the axis $X - X$.

Solution.— $I_x = I_y = \frac{d^4}{3}$ (Fig. 9).

$K = \frac{d^4}{4}$ (Fig. 72). Then from equation (1):

$$(1^\circ) I_{\alpha_1} = \frac{d^4}{3} (\cos^2 \alpha + \sin^2 \alpha) - \frac{d^4}{2} \cos \alpha \sin \alpha \\ = \frac{d^4}{3} - \frac{d^4}{2} \cdot \frac{1}{2} = \frac{d^4}{12} \quad (\text{See Fig. 14}).$$

$$(2^\circ) I_{\alpha_2} = \frac{d^4}{3} (\cos^2 \alpha + \sin^2 \alpha) - \frac{d^4}{2} \cos \alpha (-\sin \alpha) \\ = \frac{d^4}{3} + \frac{d^4}{2} \cdot \frac{1}{2} = \frac{7d^4}{12}.$$

Fig. 76.

Maximum and minimum values of I_{α} .—If a Z-bar, angle or other shape is used as a column or strut it is essential that we know the least radius of gyration of the section, and this can be obtained from the minimum moment of inertia, as $r = \sqrt{\frac{I}{A}}$; also $I_{\min}$ and $I_{\max}$ are valuable in connection with the resisting moments of beams. The following formulas give the value of α for minimum or maximum value of I_{α} :

$$\tan 2\alpha = \frac{2K}{I_y - I_x} \dots \dots \dots (5)$$

Moreover, it can be stated that the axis say $\alpha_1 - \alpha_1$ giving I_{α_1} a minimum value will be at right angle to the axis say $\alpha_2 - \alpha_2$, giving I_{α_2} a maximum value. That is, "maximum" and "minimum" axes intersect at the origin, O , at an angle of 90° . In practice it is easy to distinguish one from the other; thus, in Fig. 76, $\alpha_1 - \alpha_1$ is the "minimum" axis, and $\alpha_2 - \alpha_2$ the "maximum." The maxima and minima axes are called the "principal" axes, and in this particular case they happen to lie at an angle of 45° with the axes of X and Y . Figs. 80 and 81, following, show positions of axes for minimum values of I for the Z-bar and angle.

For a more complete discussion of moments of inertia about inclined axes see Lanza's "Applied Mechanics"; also Paper No. 1020, Trans. Am. Soc. C. E., Vol. LVI, p. 169. See also Handbook of Cambria Steel Co.

Fig. 77.—T-beam.

$$A = td + 2v(m + n)$$

$$\text{Slope } s = \frac{1}{2} = \frac{m - n}{v} = \frac{h - l}{b - t}$$

$$I_x = \frac{1}{12} [bd^3 + \frac{1}{4s} (h^4 - l^4)]$$

$$I_y = \frac{1}{12} [b^3 (d - h) + l^3 + \frac{s}{4} (b^4 - t^4)]$$

$$\text{Section modulus } S = \frac{2I_x}{d} \text{ or } \frac{2I_y}{b}$$

Ex.—What resisting moment has a beam $4\frac{1}{2}$ ins. wide by 15 ins. depth?

Ans.— $I = 281.25 \times 4 + 140.63 = 1265.63$; hence,

$$M = \frac{2}{d} I f = 168.75 f \text{ inch-lbs.} = 14.06 f \text{ ft.-lbs.}$$

If $f = 1000$, $M' = 14060 \text{ ft.-lbs.}$

31.—PROPERTIES AND TABLES OF BEAMS AND GIRDERS.

1.—WORKING STRESS, LOAD, MOMENT, SLOPE AND DEFLECTION OF BEAMS.

Notation.

f = outer fiber stress in lbs. per sq. in.;
 W = total load on beam, in lbs.;
 M'' = moment in in.-lbs. { Resisting moment;
 M' = moment in ft.-lbs. { = bending moment;
 i = tangent of angle of maximum slope of beam with the horizontal;
 v = maximum deflection of beam, in ins.;
 E = distance from neutral axis to extreme fiber, in ins.;
 E = modulus of elasticity of material;
 I = moment of inertia of section;
 L = length of beam, in feet;

l = length of beam, in inches;
 b = breadth of rectangular beam, in ins.;
 d = depth of rectangular beam, in ins.

Case A.

Case B.

Case C.

Case D.

(1)	(2)	(3)	(4)	(5)
Case.	Working Load W , in lbs.	Max. Moment M'' , in.-lbs.; M' , ft.-lbs. $M' = M'' + 12$.	Maximum Slope i = tang of ang.	Maximum Deflection v , in inches.
<i>a.—Beam of any Uniform Section; l = length of beam, in Inches = 12 L.</i>

EXAMPLES IN THE USE OF TABLE 1.

Ex. 1. (*Cases A and B combined*).—A 15-in. steel I-beam weighing 60 lb. per ft., and 10 ft. long, is fixed at one end and loaded with 10000 lb. at the other. Find the max. fiber stress f , max. moment M'' , max. slope i , max. deflection v ?

Solution.—From "Properties of I-Beams," Table 5, page 554, $I = 15$. Also, $E = 29\ 000\ 000$; $y = \frac{15}{2}$. Then, from preceding table,

	f	M''	i	v
Case Ab ($W = 10000$)	(3) $\left\{ \begin{aligned} f &= \frac{12 WLy}{I} \\ &= 14778 \end{aligned} \right.$	(3) $\left\{ \begin{aligned} M'' &= 12 WL \\ &= 1\ 200\ 000 \end{aligned} \right.$	(4) $\left\{ \begin{aligned} i &= \frac{72 WL^2}{EI} \\ &= .00408 \end{aligned} \right.$	(5) $\left\{ \begin{aligned} v &= \frac{576 WL^3}{EI} \\ &= .33 \end{aligned} \right.$
Case Bb ($W = 600$)	(3) $\left\{ \begin{aligned} f &= \frac{6 WLy}{I} \\ &= 443 \end{aligned} \right.$	(3) $\left\{ \begin{aligned} M'' &= 6 WL \\ &= 36\ 000 \end{aligned} \right.$	(4) $\left\{ \begin{aligned} i &= \frac{24 WL^2}{EI} \\ &= .00008 \end{aligned} \right.$	(5) $\left\{ \begin{aligned} v &= \frac{216 WL^3}{EI} \\ &= .00 \end{aligned} \right.$
Totals	$f = 15221$ lbs. per sq. in.	$M'' = 1\ 236\ 000$ in.-lbs.	$i = .00416$	$v = 0.33$

Ex. 2. (*Cases C and D combined*).—A wooden beam 10" x 16", and 10 ft. span, is loaded at the middle so as to produce a *total* max. outer fiber stress $f = 1000$ lbs. per sq. in. Assuming the weight of the beam at 4 lbs. per ft. B. M., find the superimposed load, max. moment M'' , max. slope i , max. deflection v ?

Solution.—Weight of beam = 800 lbs. Assume $E = 1\ 400\ 000$.

	f	M''	i	v
Case Dd ($W = 800$)	(3) $\left\{ \begin{aligned} f &= \frac{9 WL}{bd^2} \\ &= 42 \end{aligned} \right.$	(3) $\left\{ \begin{aligned} M'' &= \frac{3 WL}{2} \\ &= 18000 \end{aligned} \right.$	(4) $\left\{ \begin{aligned} i &= \frac{8 f L}{Ed} \\ &= .00022 \end{aligned} \right.$	(5) $\left\{ \begin{aligned} v &= \frac{30 f L^3}{E} \\ &= .01 \end{aligned} \right.$
Case Cd ($f = 1000 - 42$)	(3) $\left\{ \begin{aligned} W &= \frac{f bd^2}{18 L} \\ &= 9083 \end{aligned} \right.$	(3) $\left\{ \begin{aligned} M'' &= 3 WL \\ &= 408735 \end{aligned} \right.$	(4) $\left\{ \begin{aligned} i &= \frac{6 f L}{Ed} \\ &= .00385 \end{aligned} \right.$	(5) $\left\{ \begin{aligned} v &= \frac{24 f L^3}{E} \\ &= .23 \end{aligned} \right.$
Totals		$M'' = 426735$ in.-lbs.	$i = .00407$	$v = 0.24$

The weight of beam produces a max. fiber stress of 42 lbs. per sq. in. and this deducted from 1000 = 958, produced by the center load of 9083. Note that twice the center load or 18166 lbs. if uniformly distributed (producing about 1211 lbs. per lin. ft.) would produce the same fiber stress of 1000 lbs. per sq. in.

Ex. 3. (*Span and Deflection for Plastered Ceiling*).—The max. allowable deflection v of beams for plastered ceiling is $\frac{1}{360}$ of an in. per ft. of span. $v = \frac{L}{360} = \frac{l}{360}$. What general formulas may be used for wooden beams ($E = 1\ 000\ 000$) and for steel girders ($E = 29\ 000\ 000$) to represent the limiting relation? (See Note (*) for Wooden Beams on page 565.)

Solution (from Table 1).

Loading.	Wooden Beams.*	Steel Girders.
I. Uniform load W	Case Dd, (2): $W = \frac{10000 b d^3}{81 L^2}$	Case Db, (2): $W = \frac{1\ 160\ 000 d^3}{27 L^2}$
II. " "	(5): $f = \frac{10000 d}{9 L}$	(5): $f = \frac{580\ 000 d}{9 L}$
III. Center load W	Case Cd, (2): $W = \frac{6250 b d^3}{81 L^2}$	Case Cb, (2): $W = \frac{725\ 000 d^3}{27 L^2}$
IV. " "	(5): $f = \frac{12500 d}{9 L}$	(5): $f = \frac{725\ 000 d}{9 L}$

Furthermore, if the allowable outer fiber stress f for timber is 1000 lbs. per sq. in., and f for steel is 15000, we have, from II and IV:—

Loading.	Wooden Beams.*	Steel Girders.
V. Uniform load W	$L = \frac{10}{9}d = 1.55\sqrt{5}d$	$L = \frac{116}{27}\gamma = 4.296\gamma$
VI. Center load W	$L = \frac{25}{18}d = 1.94\sqrt{4}d$	$L = \frac{145}{27}\gamma = 5.370\gamma$

which are the limiting spans for plastered ceiling, and which enable us to design these spans economically.

Longitudinal Shear in Beams.—While *long* beams, even of sufficient strength to resist bending, are often limited by the deflection, as previously noted, *short* beams may fail by horizontal (longitudinal) shear. The general formula for longitudinal shear is

$$H = \frac{VQ}{I} = \frac{VA_1y_1}{I} \dots \dots \dots (1)$$

In which H = the longitudinal shearing force in lbs. per unit (lin. in.) length of beam;

V = the total vertical shear in lbs. at section considered;

Q = the statical moment in in.-lbs. of the area A_1 above the plane of shear = A_1y_1 , in which y_1 = distance from neutral axis to cen. of grav. of A_1 ;

I = the moment of inertia of beam section.

For a rectangular beam, the longitudinal shear at the neutral axis would be, if b = breadth and d = depth in inches:

$$H = V \frac{bd}{2} \cdot \frac{d}{4} + \frac{bd^3}{12} = \frac{3}{2} \cdot \frac{V}{d} \dots \dots \dots (2)$$

and the intensity of shear per square inch would be

$$\frac{H}{b} = \frac{3}{2} \cdot \frac{V}{bd} \dots \dots \dots (3)$$

Note that the vertical shear V at any point of a beam is equal to the differential coefficient of the bending moment at that point; thus,

$$V = \frac{dM}{dx} \dots \dots \dots (4)$$

x being the distance from left-hand end of beam to section considered.

Problem:—A wooden beam 12 x 12 ins., weighing 600 lbs. ($=w$), supports a uniform load of W lbs. What will be the maximum value of W , so that the maximum intensity of shear, $H + b$, (at the neutral axis,) shall not exceed 50 lbs. per sq. in.?

Solution:—The maximum vertical shear (at the end of the beam) equals $V = \frac{W+w}{2}$. Substituting this value of V in equation (3), we have,

$$\text{Intensity of shear} = \frac{H}{b} = \frac{3}{2} \cdot \frac{W+w}{2bd} = 50$$

Hence, by substitution, $W = 9600 - 600 = 9000$ lbs. *Ans.* (See also, Example 1, bottom of page 567.)

Note that the length of span, in the above problem, is not a factor in longitudinal shear.

* Note that W and f are directly proportional to the modulus of elasticity, E , of the material, which, in the present instance, is assumed at 1 000 000. For any other modulus, as E_1 , multiply above values by

$\frac{E_1}{1\,000\,000}$. See Sec. 28, Strength of Materials, Table 7, page 495.

**2.—UNIFORMLY DISTRIBUTED LOADS W IN POUNDS
ON RECTANGULAR BEAMS 1 INCH WIDE
PRODUCING EXTREME FIBER STRESS $f=1000$ LBS. PER SQ.**

$$\left(\text{By Formula, Case Dd (2): } W = \frac{fbd^2}{9L} = \frac{1000d^2}{9L} \right).$$

For any other fiber stress, as f_1 , multiply values in table by $\frac{f_1}{1000}$.

Note.—For allowable fiber stresses in Wooden Beams, see Sec. 28, Strength of Materials, Table 7, column 8, page 495. For bridge stringers use safety factor 6; for floor beams, 5.

Remember that W is proportional to d^3 and inversely proportional to L ; thus the range of the table may be extended greatly.

EXAMPLES IN USE OF TABLE 2.

Example 1.—In the problem at bottom of page 565, longitudinal shear, we find that a 12 x 12-in. wooden beam will support a total load (including weight of beam = 600 lbs.) of 9600 lbs. Find the maximum length of span so that the outer fiber stress f shall not exceed 1000 lbs. per square inch.

Solution.—From the data given, a beam 12 ins. wide and 12 ins. deep will support a total load of 9600 lbs.; hence, for the same depth of beam, each one inch in width will support $9600 \div 12 = 800$ lbs. Now, in the last column (the 12" column) on preceding page we find that the load 800 corresponds to a span of 20 ft. Ans.

Example 2.—In the preceding Example, find the maximum length of span so that the outer fiber stress f shall not exceed 600 lbs. per square inch.

Solution.—Corresponding length of span,

$$L = 20 \frac{f_1}{f} = 20 \frac{600}{1000} = 12 \text{ ft. Ans.}$$

Example 3.—A beam supports a load $W = 9600$ lbs., producing an outer fiber stress $f = 1000$. What load W_1 will it support if the allowable fiber stress f_1 is increased to 1200 lbs. per square inch?

Solution.— W is proportional to f ; hence

$$W_1 = W \frac{f_1}{f} = 9600 \frac{1200}{1000} = 11520 \text{ lbs. Ans.}$$

3.—BEAM BOX GIRDERS (STEEL)—Concluded.

* Based on allowable fiber stress of 15000 lbs. per sq. in. For 16-ft. span, divide total load by 1.6; 20-ft. span, divide by 2; 30-ft. span, divide by 3; etc. Note that total load W includes weight of girder, which must be deducted to obtain superimposed load.

Problem.—Required to design a beam box girder of 16-ft. clear span, for a superimposed load which produces a maximum bending moment $M'' = 3,150,000$ in.-lbs.; with a total allowable fiber stress $f = 14400$ lbs. per square inch.

Solution.—(See Table 1, page 562, for formulas.) From the general formulas (3) we have,

$$(1.) \text{ For the superimposed load: Sec. mod. } S = \frac{I}{y} = \frac{M''}{f} = \frac{3150000}{14400} = 218.75$$

From the above table this value of S calls for 15" - 42# beams with plates.

$$(2.) \text{ For the weight of the girder: Sec. mod. } S = \frac{I}{y} = \frac{M''}{f} = \frac{Wl}{8f} = \frac{wl^2}{8f},$$

in which w = the weight in lbs. per lin. ft. of girder. From the above table, we may assume $w = 183$; then $S = \frac{183 \times 256 \times 12 \times 12}{8 \times 14400} = 58.55$

(1 and 2.) **Ans.**—Use two 15" - 42# beams and two 14 × 1" plates: For required $S =$

The diff. in weights in preceding column indicated by a star (*) does not include separate rivets for assembling the beams into girders.

Reinforced Concrete Beams.—The following Working Stresses for Static Loads are recommended by the Special Committee of the Am. Soc. C. E., on Concrete and Reinforced Concrete. (See Trans. A. S. C. E., Vol. LXVII., page 452.) For Notation and Formulas, see Sec. 25, Masonry, page 446. For working stresses for columns, see Sec. 32, Columns, page 609.

Compressive Strength of Stone Concrete.—Average, 2000 lbs. per sq. in. at 28 days, when tested in cylinders 8 ins in dia. and 16 ins. long, under laboratory conditions of manufacture and storage.

Bearing.—650 lbs. per sq. in. on 2000-lb. concrete.

Bending.—Compression on extreme fiber of beam, 650 lbs. per sq. in. for 2000-lb. concrete; adjacent to support of continuous beams, 750 lbs. per sq. in.

Pure Shear.—When uncombined with compression normal to the shearing surface, and with all tension normal to the shearing plane provided for by metal reinforcement, 120 lbs. per sq. in. on 2000-lb. concrete.

Shear with Diagonal Tension.—In beams without diagonal reinforcement, 40 lbs. per sq. in. for 2000-lb. concrete.

Bond.—Between concrete and plain reinforcing bars, 80 lbs. per sq. in. for 2000-lb. concrete; between concrete and drawn wire, 40 lbs. per sq. in.

Reinforcement.—Tensile stress in steel shall not exceed 16000 lbs. per sq. in.

EXCERPTS AND REFERENCES.

Tests of Reinforced Concrete Beams (By W. K. Hatt. Proc. A. S. T. M., 1902; Eng. News, July 17, 1902).—This is a very complete Paper and contains numerous diagrams and tables of the tests, with discussion of same; also includes Hatt's formula for reinforced concrete beams.

Computing the Strength of Reinforced Concrete Beams (By Edwin Thacher. Eng. News, Feb. 12, 1903).—Discussion of above. "It is the practice of the writer to give the concrete a certain factor of safety at the end of one month, and to give the steel the same factor of safety as the concrete at the end of six months, as it is evident that if there was not an excess of steel in one month, there would be a deficiency after the concrete gained its full strength. For example, to design a slab of length $l=6$ ft., using 60000-lb. steel, for a total load w of 400 lbs. per sq. ft., that shall have a factor of safety of 4 in one month, but in which the tensile strength of the steel shall be equal to the compressive strength of the concrete after 6 months:—Then, the distance from top of beam to center of reinforcement

$=d=\sqrt{pw+883}=\sqrt{6\times6\times400+883}=3.92$ ins.; or, if the center of bars is 1.08 ins. from bottom of concrete, the total height $h=3.92+1.08=5$ ins., and the area of metal for 1" width of beam $=A=d+90=3.92+90=.0435$ sq. in. Using Thacher bars, having original diam. of $\frac{1}{4}$ in., area = .276, weight per ft. = .94 lb., dist. c. to c. bars = $.276+.0435=6.35$ ins." Gives tabulated formulas for calculating rein. conc. beams ($E=30,000,000$).

Table of Tests on the Union Between Concrete and Steel (At Mass. Inst. Tech. Eng. News, May 5, 1904).—Types of rods used in the tests were: Thacher, Ransome, Johnson, and plain round and square rods.

Tests of Reinforced Concrete Beams (By Arthur N. Talbot. Proc. A. S. T. M., 1904. Eng. News, Aug. 11, 1904).—Types of rods used in the tests were: Thacher, Ransome, Johnson, Kahn, and plain round and square rods. Table and Diagrams.

Tests of Reinforced Concrete Beams and Floors (At St. Louis Exposition. By R. L. Humphrey. Eng. News, Sept. 21, 1905).—Illustrated diagrams of beams tested.

The Design of Reinforced Concrete Structures (By F. W. Keyser and E. L. Heidenreich; and C. A. P. Turner).—Discussion.

Notes on the Stress-Deformation Curve in Concrete Beams (By N. Wernskiold. Eng. News, April 5, 1906).—Diagrams and formulas.

Economic Design of Reinforced Concrete (By F. W. Hanna. Eng. News, Feb. 21, 1907).—Gives a table of the economical working stresses and percentages of steel reinforcement for varying relative costs of steel and concrete—calculated for unit compressive working stress in outer fiber of concrete = 6000 lbs. per sq. in., and for $r=E_s+E_c=10$. (See, also, Eng. News, June 20, 1907.)

Diagram for Proportioning Reinforced Concrete Beams (By A. H. Perkins. Eng. News, April 25, 1907).—It is a compound diagram, comprising (1) a set of lines giving the bending moment in a simple beam for any span and any load per foot of length and per inch of width; (2) a set of lines giving the corresponding values of breadth and depth of reinforced concrete beam to resist this moment. This latter part of the diagram is based on the following unit values:—Max. comp. in concrete $c=600$ lbs. per sq. in.; tension in steel $s=12,000$ lbs. per sq. in.; $E_s+E_c=n=10$; percentage of steel $p=0.95\%$; moment capacity of beam b inches wide and d inches deep $=M=100 bd^2$. The stress-strain curve of concrete is assumed to be between the straight line and the parabola. (See, also, Tiechman's formula and diagrams in Eng. News, July 11, 1907.)

Reinforced Concrete T-Beam and Column Tests (At Univ. of Ill. By A. N. Talbot. Bulletins Nos. 10 and 12 of the Eng. Exper. Station, Univ. of Ill.; Eng. News, July 11, 1907).—Diagrams of beams and columns tested, and tables of tests.

Tests of Adhesion of Steel to Concrete in Beams (By L. J. Johnson. Jl. of Assn. of Eng. Soc. for June, 1907; Eng. News, Aug. 15, 1907).—Tables and diagrams.

Effect of Time Element in Loading Reinforced Concrete Beams (By W. K. Hatt. Proc. A. S. T. M., 1907; Eng. News, Oct. 24, 1907).—Tables and diagrams.

Section Modulus Diagram for Plate and Lattice Girders (By L. R. Shellenberger. Eng. News, Nov. 26, 1908).—The diagram is for flange angles $6^\circ \times 6^\circ$; and for section moduli up to 3400 ins., and depth of web up to 85 ins.

Tests of Standard I Beams and Special I Beams and Girder Beams (By Edgar Marburg. Proc. A. S. T. M., Vol. IX., 1909; Eng. News, Aug. 12, 1909).—Illustrations, diagrams and tables. Generally speaking, the modulus of rupture in lbs. per sq. in. decreases as the depth of the girder increases. In actual practice, however, the beams would be supported laterally, at intervals, which might affect the comparative results of the experiments.

Moments in Continuous Concrete Beams Under Uniform Loading (By R. E. Spaulding. Eng. News, Sept. 30, 1909).—Numerous formulas and diagrams.

Slide-Rule for Reinforced-Concrete Slabs (By A. W. French. Eng. News, Feb. 3, 1910).—Illustrated.

Table of Moments of Inertia of Flat Rectangles (By H. Loewenhorn. Eng. News, Feb. 24, 1910).—For widths b (advancing by one inch from 6 to 40 ins.) and depths d (advancing by sixteenths of an inch from $\frac{1}{4}$ to 3 inches).

Some Deductions from Warburg's I-Beam Tests (By C. J. Tilden. Eng. News, Feb. 24, 1910).—With discussion by Edgar Marburg.

Comparison of Methods of Computing the Strength of Flat Reinforced Concrete Plates (By A. B. MacMillan. Paper, Natl. Assn. Cement Users, Feb. 21-25, 1910; Eng. News, Mar. 31, 1910).—Illustrated. Discussions: Cantilever method; Turneure and Maurer method; Grashof's Analysis; Mensch's method; Turner's method; Macmillan method; Mushroom floor.

Interesting Illustrations.

32.—PROPERTIES AND TABLES OF COLUMNS.

General Stresses.—A column is a pillar or strut acting mainly in compression; but in addition to the direct compressive stress, it has also to resist, to a greater or less extent, shearing and bending. To what degree the shearing stresses enter into and affect a column we are unable to say, and no column formula has yet been devised which includes the shearing effect of the stresses. Indeed, omitting the effect of shear altogether, it is a mooted question whether we are able even to combine rationally in a single formula the effects of direct compression and bending.
